Department of Mathematics the University of Tokyo

0. Introduction

In number theory, the analytic properties of the critical values of automorphic $L$-functions are important in the conjectural framework of Deligne and Beilinson. For previous work of Harder [H], to compute the period integrals of the Eisenstein cohomology classes over the fundamental cycles formed by summing over a genus, we can get the special values of the associated $L$-function, together with some explicitly computed local factors. In this case, He considered the cohomology on the arithmetic quotients of the upper half plane of degree $n$. However, he has not come to consider its Eisenstein cohomology classes and has not prove the Deligne’s conjecture. To understand the arithmetic of certain special values of $L$-functions based on the Deligne’s conjecture, we should treat the Eisenstein cohomology of other manifold. In this article, we understand the analytic properties of such an Eisenstein cohomology classes to prove the Deligne’s conjecture on the special values of the associated $L$-functions.

Let $\pi$ be a cuspidal representation of GL(2). Our main object of this article is the exterior square $L$-functions of $\pi$ defined by using the standard $L$-function

\[(0.1) \quad L(s, \pi) = \prod_{\alpha_i \in \mathbb{C}} (1 - \alpha_i p^{-s})^{-1}, \alpha_i \in \mathbb{C}\]

of $\pi$. We denote

\[(0.2) \quad L(s, \pi, \wedge^2) = \prod_{1 \leq i < j \leq 2} (1 - \alpha_i \alpha_j p^{-s})^{-1}\]

the exterior square $L$-functions on GL(2). To prove the Deligne’s conjecture on the critical values of the exterior square $L$-functions, we find its period integral representation and confirm the analytic properties of suitable Eisenstein cohomology classes.

Typeset by \LaTeX
Since we will denote more precisely, our interesting situation confine \( G \) to \( \text{Sp}(2, \mathbb{Q}) \). Let \( X \) be a symmetric spaces which is a quotient of \( G(\mathbb{R})/K_{\infty} \). Here \( K_{\infty} \) is a maximal compact subgroup of \( G(\mathbb{R}) \). \( X \) is identified with the Siegel upper half space of degree 2. We take \( \Gamma \) be a torsion free arithmetic subgroup of \( G \). It naturally acts on \( X \) for the identification. The cohomology classes of \( H^*(\Gamma \backslash X) \) arise from classes on the boundary of the Borel-Serre compactification of \( \Gamma \backslash X \). Since the compactification has the same homology type as \( \Gamma \backslash X \), there is a restriction map from the cohomology of \( \Gamma \backslash X \) to the cohomology of the boundary. The boundary components are parameterised by \( \Gamma \)-conjugacy classes of parabolic subgroups and are homotopic to quotients of \( X \) by a subgroup of \( \Gamma \). The cohomology group \( H^*(\Gamma \backslash \bar{X}, \mathbb{C}) \) on the compactification decomposes the direct product of the cuspidal cohomology \( H^*_{\text{cusp}}(\Gamma \backslash \bar{X}, \mathbb{C}) \) and so called Eisenstein cohomology \( H^*_{\text{Eis}}(\Gamma \backslash \bar{X}, \mathbb{C}) \). It is known that the Eisenstein cohomology classes are represented by its suitable residue or the first term. Then our aim of this paper is to realize its classes using well-known arithmetic functions like Gamma function and zeta function and calculate its period integrals to describe the special values of automorphic \( L \)-functions.

Specially, if the degree of the cohomology group is 3, J. Schwermer showed in [Sc] that the cohomology classes of \( H^3(\Gamma \backslash \bar{X}, \mathbb{C}) \) are represented by the residue of a Eisenstein series \( E(g, s) \) where its flat section is in the induced representation of the minimal parabolic subgroup of \( G \) (after, we will call it the minimal parabolic Eisenstein series) and the constant terms of the Eisenstein series of the maximal parabolic subgroups of \( G \). Then first we will give the formula of the residue of the minimal parabolic Eisenstein series (Theorem 4). In order to give the explicit formula of the residue, it is necessary to describe Fourier expansion of the minimal parabolic Eisenstein series \( E(g, s) \) along the minimal parabolic subgroup \( P \) of \( G \) and to carry out the differentiate for \( s \) (Theorem 3). However the Fourier expansion of the real analytic Siegel modular forms along \( P \) is not known, we will extend the results of [Na] for the holomorphic Siegel modular forms (Theorem 2).

Our main theorem of this paper is to compute \( H = \text{GL}(2) \times \text{GL}(2) \)-period of the residue of the minimal parabolic Eisenstein series to bring out that it is the pure and simple critical value of the exterior square \( L \)-function \( L(1/2, \pi, \wedge^2) \) (Theorem 5).

**Theorem.** We define \( \Omega_{\varphi^{(2)}} \) be the period integral of the flat section included in the minimal parabolic Eisenstein series \( E(g, s) \). Then we have

\[
(0.3) \quad \Omega_{\varphi^{(2)}} \cdot \int_{H(\mathbb{Q}) \backslash H(\mathbb{A})} \text{Res}_{s=1} E^*(h, s) dh = L(1/2, \pi)L(1, \pi, \wedge^2),
\]

where \( L(1/2, \pi) \) be the special value of the standard \( L \)-function of automorphic cuspidal representation \( \pi \).

The flow of its calculation is as follows. We use two theorems. One of it is the minimal parabolic Eisenstein series can be decomposed as the classical Eisenstein series on \( \text{GL}(2) \) and the Siegel-Eisenstein series associated to the maximal parabolic subgroup of \( G \) (Theorem 1), and the other one is the period becomes Bump and Friedberg’s Rankin-Selberg integral referred in [BF]. Since the analyticity of it follows from the residue of the minimal parabolic Eisenstein series, then we hope to prove the Deligne’s conjecture on the critical values of the exterior square \( L \)-functions to future application.

During writing this paper, the author was supported by Grants-in-Aid for young scientists (S) for JSPS. The project title is “Strategic Research to solve certain
conjectures in Arithmetic Geometry”, the number of it is 21674001 and its principal investigator is Pf. Kenichi Bannai belonging to Keio university, department of mathematics. I appreciate that S. Matsumoto gave advice about the program of the Iwasawa decomposition in Matlab.

Below, $\sigma(X)$ is set to the usual trace of the matrix $X$ and $\delta(X)$ is the determinant of it. And $e(\alpha)$ means $e^{2\pi \sqrt{-1}\alpha}$.

I. Minimal parabolic Eisenstein series for symplectic group

I-1. Group structure.

Let $G$ be a symplectic group of degree 2 over the rationals $\mathbb{Q}$ which is defined by

$$G = \text{Sp}(2, \mathbb{Q}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}(2, \mathbb{Q}) \mid \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \right\}.$$

Take its analytic subgroups $N$ and $A$ of $G$ for

$$N = N_0 \ltimes N_2$$

and

$$A = \{ a(p) = \text{diag}(a_1, a_2, a_1^{-1}, a_2^{-1}) \mid a_i > 0 \} ,$$

where $N$ is the maximal unipotent radical and $A$ a maximal split torus of $G$. Then $G$ has the Iwasawa decomposition $G = NAK$ for a fixed maximal compact subgroup $K = K_\infty \times \prod_{v < \infty} K_v$, where $K_\infty = G(\mathbb{R}) \cap O(4) \cong U(2)$ and $K_v = G(\mathbb{Z}_v)$ for $v < \infty$.

Let $M = Z_K(A)$ be the centraliser of $A$ in $K$

$$M = \{ \text{diag}(\varepsilon_1, \varepsilon_2, \varepsilon_1, \varepsilon_2) \mid \varepsilon_1, \varepsilon_2 \in \{ \pm 1 \} \}.$$

Then the minimal parabolic subgroup $P = NAM$ of $G$ has the Langlands decomposition which is known by [L].

In this section, we recall the principal series representation of $G$ for the minimal parabolic subgroup $P$.

Let $\mathfrak{a}$ be the Lie algebra of $A$. For $\lambda = (\lambda_1, \lambda_2) \in \mathfrak{a}_c^* = \text{Hom}_\mathbb{R}(\mathfrak{a}, \mathbb{C}) \cong \mathbb{C}^2$, we define a modulus quasi-character $e^\lambda : P \to \mathbb{R}_{>0}$ of $P$ by

$$e^\lambda(a(p)) = \exp(\lambda \log a(p))$$

for the Langlands decomposition $p = na(p)m$, $n \in N$, $a(p) \in A$ and $m \in M$.

The irreducible unitary representations $\sigma$ of $M$ are given by products of sign representations. It is specified by

$$\varepsilon_1 = \sigma(\text{diag}(-1, 1, -1, 1)) \quad \text{and} \quad \varepsilon_2 = \sigma(\text{diag}(1, -1, 1, -1)).$$

For an irreducible cuspidal automorphic representation $(\pi, V_\pi)$ of $G$, there exists cuspidal data $(P, 1_N \otimes e^{\lambda + \rho} \otimes \sigma)$, where $\rho$ is the half-sum of the positive roots of $P$. 
Definition 1. Let $\sigma$ be the irreducible unitary representation of $M$. For $\lambda \in a^*_C$, we define the principal series representation of $G$ as an induced representation

\begin{equation}
\text{Ind}_G^G(1_N \otimes e^{\lambda+\rho} \otimes \sigma) = \{ \varphi : G \to V_\pi \mid \varphi(pg) = e^{\lambda+\rho}(a(p))\sigma(m)\varphi(g), \forall(p,g) \in P \times G \}.
\end{equation}

We call function $\varphi : \mathbb{C} \times G \to \mathbb{C}$ a flat section of $\text{Ind}_G^G(1_N \otimes e^{\lambda+\rho} \otimes \sigma)$ when it satisfies the following conditions: For all $s \in \mathbb{C}$, $\varphi(s, \cdot) : G \to \mathbb{C}$ belongs to the space of the induced representation and its restricted in $K$ is not depend on $s \in \mathbb{C}$.

Definition 2. Let $\varphi_{\lambda+\rho} \in \text{Ind}_G^G(1_N \otimes e^{\lambda+\rho} \otimes \sigma)$ be a flat section. The minimal parabolic Eisenstein series for $G$ is defined by

\begin{equation}
E(g, s) = \sum_{\gamma \in P \backslash G} \varphi_{\lambda+\rho}(s, \gamma g).
\end{equation}

This series is absolutely convergent for $\text{Re } s > 3/2$.

In this subsection, we consider the relation between the minimal parabolic Eisenstein series and the Siegel-Eisenstein series of $G$. This relation is studied for some time, for example, is written in [Ba], [Sa] and [GMRV], however there is no evident paper to give an explicit formula of its Fourier expansion, prove its functional equation and give some information about poles. Then we bring out the relation among Siegel-Eisenstein series where its classical Siegel-Fourier expansion is extensively considered.

Now, let $P_2$ be the Siegel maximal parabolic subgroup of $G$. It has the Levi decomposition $P_2 = N_2 A_2 M_2$, where

\begin{equation}
N_2 = \left\{ n(x) = \begin{pmatrix} 1_2 & x \\ 0_2 & 1_2 \end{pmatrix} \mid x = t x \right\}, \quad A_2 = \{ \text{diag}(a, a^{-1}, a^{-1}) \mid a > 0 \}
\end{equation}

and

\begin{equation}
M_2 = \left\{ m(a) = \begin{pmatrix} a & 0_2 \\ 0_2 & t a^{-1} \end{pmatrix} \mid a \in \text{SL}^\pm(2) \right\}.
\end{equation}

We can also define the Siegel-Eisenstein series for $G$ using a flat section $\varphi^{(2)}_{\lambda_2} \in \text{Ind}_{P_2}^G(1_{N_2} \otimes e^{\lambda_2+\rho_2} \otimes \sigma_2)$ for $\rho_2 = (3/2, 3/2)$,

\begin{equation}
E_2(g, s) = \sum_{\gamma \in P_2 \backslash G} \varphi^{(2)}_{\lambda_2+\rho_2}(s, \gamma g).
\end{equation}

The first theorem of this paper is to show the relation between the minimal parabolic Eisenstein series and the Siegel-Eisenstein series.

Theorem 1. Let $\varphi^{(2)}_{\lambda+\rho} \in \text{Ind}_{P_2}^G(1_{N_2} \otimes e^{\lambda+\rho} \otimes \sigma_2)$ be a flat section and $f$ be a natural embedding from $\text{GL}(2)$ to $P_2$ as $A \mapsto \begin{pmatrix} A & 0_2 \\ 0_2 & t A^{-1} \end{pmatrix}$. For the embedding, we
where the isomorphism $P$ of $\text{Ind}_{B}^{\text{GL}(2)}$ is decomposed as follows.

\begin{equation}
\varphi_{\nu+i+\rho_2}(s, \delta \tilde{f}^{-1}(p_2)),
\end{equation}

where $B$ is the standard Borel subgroup on $\text{GL}(2)$ and $\varphi_{\nu+i+\rho_2}$ is a flat section in $\text{Ind}_{B}^{\text{GL}(2)}(1_{N_B} \otimes e_{B}^{\nu+i+\rho_2} \otimes \sigma_B)$. Then the minimal parabolic Eisenstein series $E(g, s)$ is decomposed as follows.

\begin{equation}
E(g, s) = \sum_{\gamma \in P_2 \setminus G} \varphi_{\lambda+\rho}(s, \gamma g) \varepsilon(\gamma g, s).
\end{equation}

**Proof.** Since the Siegel maximal parabolic subgroup $P_2$ contains the minimal parabolic subgroup $P$, we can replace the first summation with $B \setminus \text{GL}(2)$. The first isomorphism theorem says that $P_2 \setminus P_2 \cong B \setminus \text{GL}(2)$ and we can replace the first summation with $B \setminus \text{GL}(2)$.

From the character formula for the induced representation, if we consider the inclusion relation $P \subset P_0 \subset G$, then we have an isomorphism $\text{Ind}_{P}^{G}(1_{N} \otimes e^{\lambda+\rho} \otimes \sigma) \cong \text{Ind}_{P_2}^{G} \left( \text{Ind}_{P_0}^{P_2}(1_{N} \otimes e^{\lambda+\rho} \otimes \sigma) \right)$ which is called induction in stages.

The Borel subgroup $B$ has the Langlands decomposition $B = N_B A_B M_B$ such that

\[ N_B = \left\{ \left( \begin{array}{cc} 1 & b \\ 0 & 1 \end{array} \right) \mid b \in \mathbb{R} \right\}, A_B = \left\{ \left( \begin{array}{cc} a_1 & 0 \\ 0 & a_2 \end{array} \right) \mid a_i \in \mathbb{R}_{>0} \text{ and } |a_1| \neq 1, |a_2| \neq 1 \right\}. \]

and

\[ M_B = \left\{ \left( \begin{array}{cc} a_1 & 0 \\ 0 & a_2 \end{array} \right) \mid a_i \in \mathbb{R}_{>0} \text{ and } |a_1| = |a_2| = 1 \right\}. \]

We also define $\sigma_B$ the irreducible unitary representation of $B$ and $e_{B}^{\nu}$ the modulus quasi-character of $B$ for $\nu \in \text{Hom}_{\mathbb{R}}(a_B, \mathbb{C})$. Since the image of a representative $\alpha$ of $B \setminus \text{GL}(2)$ by $\tilde{f}$ becomes a representative $\tilde{f}(\alpha)$ of $P \setminus P_2$, if we take $\varphi'$ an element of $\text{Ind}_{P_2}^{G}(1_{N} \otimes e^{\lambda+\rho} \otimes \sigma)$ and define $\varphi^{(1)}(\alpha) = \varphi'(\tilde{f}(\alpha))$, for $\alpha \in [A]$, then we have the isomorphism

\[ \varphi_{\nu+i+\rho_2}^{(1)} \in \text{Ind}_{B}^{\text{GL}(2)}(1_{N_B} \otimes e_{B}^{\nu+i+\rho_2} \otimes \sigma_B) \cong \text{Ind}_{P_2}^{G}(1_{N} \otimes e^{\lambda+\rho} \otimes \sigma) \cong \varphi_{\lambda+\rho}', \]

where $\iota = (1/2, -1/2)$ be the half-sum of positive roots for $\text{GL}(2)$.

For all $g \in G$, we have

\[ E(g, s) = \sum_{\gamma \in P_2 \setminus G} \varphi_{\lambda+\rho}'(s, \gamma g) \varphi_{\lambda+\rho}^{(1)}(s, \gamma_1(\gamma_2 g)|p_2) \]

\[ = \sum_{\gamma \in P_2 \setminus G} \varphi_{\lambda+\rho}'(s, \gamma g) \varphi_{\nu+i+\rho_2}(s, \delta \tilde{f}^{-1}(\gamma_1) \tilde{f}^{-1}(\gamma_2 g)). \]

The second summation is the Eisenstein series on $\text{GL}(2)$. □
II. Fourier expansion of the Eisenstein series along the minimal parabolic subgroup

However the classical Fourier expansion along the maximal parabolic subgroup are well-known, little is known concerning the Fourier expansion along the minimal parabolic subgroup $P$. One of the reason of it is that the unipotent radical $N$ of $P$ is non-abelian. We should extend the theory of Fourier analysis on non-abelian groups. According to the previous study of H. Narita discussed about an expansion of vector-valued holomorphic Siegel modular forms in [Na], the Fourier coefficients of the Fourier expansion along minimal parabolic subgroup are related to the maximal one. We should extend the results for the real analytic Eisenstein series. Also we prove the relation between the Fourier coefficients of the Fourier expansion along the minimal parabolic subgroup and the Siegel maximal parabolic subgroup as an expansion of the study of Narita and calculate the Fourier expansion of the real analytic Eisenstein series obtained in section 1, coming down to the maximal one.

II-1. Construction of the Fourier expansion along the minimal parabolic subgroup.

We define $(π, H_π)$ be the spherical principal series representation of $G$ and $(τ, V_τ)$ be the irreducible finite dimensional representation of $K$. Let $ι$ be the inclusion map from $τ$ to $π_K$ where $π_K$ be the $K$-finite vectors in $π$. Then we can define a generalised Whittaker function as an image of the following map:

$$(2.1) \quad W_{k,T} \in \text{Hom}_{(\mathfrak{g},K)}(π_K, C^∞_{\eta_T}(N\backslash G)_K) \to \text{Hom}_K(τ, C^∞_{\eta_T}(N\backslash G)_K) \ni W_{k,T} \circ ι,$$

where

$$(2.2) \quad \eta_T = L^2\text{-Ind}_{\mathcal{M}}^N(T \log)$$

and

$$(2.3) \quad C^∞_{\eta_T}(N\backslash G)_K = \left\{ W_{k,T} : G \to H^∞_{\eta_T} \left| W_{k,T}(ng) = \eta_T(n)W_{k,T}(g), \text{ K-finite} \right. \right\}$$

for $H_{\eta_T}$ the representation space of $\eta_T$ and $H^∞_{\eta_T}$ the space of $C^∞$-vectors in it. We remark that the space $\text{Hom}_K(τ, C^∞_{\eta_T}(N\backslash G)_K)$ is equivalent to the following space such that

$$(2.4) \quad \left\{ W_{k,T} : G \to H^∞_{\eta_T} \left| W_{k,T}(ngk) = \eta_T(n)τ(k)W_{k,T}(g) \right. \right\}.$$

The explicit formula of the generalised Whittaker function at archimedean place was given by Niwa in [Ni], Theorem 1 and Proposition 2.

We take an arithmetic subgroup $Γ$ of $G$ which implies that the $\mathbb{Q}$-structure comes from such of $G$ and $N \cap Γ = NΓ = (N_0 \cap Γ) \rtimes (N_2 \cap Γ)$. Since $N_Γ \backslash N$ is compact, its $L^2$-space is decomposed as the Hilbert space direct sum.

**Proposition 1.** Let $\tilde{N}$ is the unitary dual of $N$. We have

$$L^2(N_Γ \backslash N) \cong \bigoplus_{(η,H_η)} \text{Hom}_N(η, L^2(N_Γ \backslash N)) \otimes H_η.$$
Proof. Its proof is described in [GGP], Chapter I. section 2.3. □

As same as in [Na], if we choose a basis of $\text{Hom}_N(\eta, L^2(N_1 \setminus N))$ and decide the multiplicity of $\eta$ in $L^2(N_1 \setminus N)$, then we can describe the Fourier expansion of the real analytic Eisenstein series along the minimal parabolic subgroup $P$ on $G$. Before stating our result, we prepare some notation.

Let $S_2$ be a set of positive definite symmetric matrices of degree 2 with rational coefficients. We denote by $\bar{S}_2$ the closure of $S_2$ in $V$. Since $\text{tr}(u, v)$ for $u, v \in V \cong N_2$ is a non-degenerate bilinear form on $V$, we define the dual lattice of $V = V \cap \Gamma = N_2 \cap \Gamma$ such that

$$S_2^\vee = \{ T \in \bar{S}_2 \mid \text{tr}(T, S) \in \mathbb{Z}, \forall S \in V \}.$$  

Consider the natural action of the maximal unipotent radical $U_2(\mathbb{Q}) = \left\{ \left( \begin{array}{cc} 1 & b \\ 0 & 1 \end{array} \right) \right\}$ of $GL(2, \mathbb{Q})$ such that $(v, u) \mapsto tuvu$ for all $u \in U_2(\mathbb{Q})$, we define

$$S_2^\vee \sim = S_2/U_2(\mathbb{Q}).$$

Since $U_2 \cap \Gamma \cong U_2(\mathbb{Z}) \cong N_0 \cap \Gamma$, for an $S \in S_2^\vee$, we define

$$M_0^\vee, S = \{ T \in S_2^\vee \mid t u T u = S, \exists u \in U_2(\mathbb{Q}) \}/U_2(\mathbb{Z}).$$

For $T \in M_0^\vee, S$, let $m_T$ be a maximal subordinate subalgebra : a maximal left subalgebra containing the characteristic subalgebra and excluding the central generator, and $M_T = \exp(m_T)$.

Proposition 2. Let $F$ be a real analytic Eisenstein series on $G$ of weight $k$ with respect to $\Gamma$. For any $n \in N$ and $g \in G$, the Fourier expansion of $F$ along $P$ is given by

$$F(ng) = \sum_{S \in S_2^\vee, \sim} \sum_{T \in M_0^\vee, S} F_{S, T}(g) \Theta_T(W_{k, T}(\cdot))(n),$$

where

$$\Theta_T(W_{k, T}(\cdot))(n) = \sum_{\gamma \in N_\Gamma \cap M_T \setminus N_\Gamma} W_{k, T}(\gamma n) \quad \text{and} \quad F_{S, T}(g) = W_{k, T}(1 \cdot g)^{-1}.$$
**Theorem 2.** Let $F$ be a real analytic Eisenstein series on $G$ of weight $k$ with respect to $\Gamma$. We take $T \in S^\vee_2$ belonging to $M_{0, \infty}(S)$ with some $S \in S^\vee_2$. Define the Fourier expansion of $F$ along the minimal parabolic subgroup $P$ is

$$(2.11) \quad F(g) = \sum_{S \in S^\vee_2} \sum_{T \in M_{0, \infty}(S)} F_{S,T}(g) \Theta_T(W_{k,T}(\cdot))(n)$$

and the maximal parabolic subgroup $P_2$ is

$$(2.12) \quad F(g) = \sum_{S \in S^\vee_2} F_S(g)e(\sigma(Sx)).$$

Then the relations of the both Fourier coefficients are given by

$$(2.13) \quad F_{S,T}(g) = F_S(g), \quad \text{and} \quad F_{S,T}(g) = F_{u,Su}(g), \quad \text{for every } u \in U_2(\mathbb{Z}).$$

**Proof.** It is done to replace $N$ with $N_2$ in the formula of the Fourier expansion of $F$ along $P$ in the previous proposition. Before all, in the part of $\Theta_T((W_{k,T}(\cdot))(n))$, it can be calculated as follows. For all $n(x) \in N_2 \subset P_2$,

$$\Theta_T((W_{k,T}(\cdot))(n(x)) = \chi_T(n(x))W_{k,T}(\cdot) = W_{k,T}(n(x))$$

$$= \eta_T(n(x)) = e(\sigma(Tx)).$$

Compare with the formulas of both Fourier expansions, we obtain the statement. \(\square\)

**II-2. Calculation of the Fourier expansion.**

According to the previous subsection, we have to calculate the Fourier expansion as follows:

$$(2.14) \quad E(g, s) = \sum_{S \in S^\vee_2} \sum_{T \in M_{0, \infty}(S)} E_{S,T}(g) \Theta_T(W_{k,T}(\cdot))(n),$$

where the Fourier coefficients $E_{S,T}(g)$ is expressed as

$$E_{S,T}(g) = \int_{N_2 \setminus N_2(k)} \sum_{\gamma \in P_2 \setminus G} \varphi^2_{\lambda+\rho}(s, \gamma n(x)m((\begin{smallmatrix} a_1 & a_2 u \\ 0 & a_2 \end{smallmatrix})))$$

$$\times e(\gamma n(x)m((\begin{smallmatrix} a_1 & a_2 u \\ 0 & a_2 \end{smallmatrix})), s) e(-\sigma(Sx))dn(x)$$

for a decomposition $g = n(x)m((\begin{smallmatrix} a_1 & a_2 u \\ 0 & a_2 \end{smallmatrix})), k \in G$. Below, $E_{S,T}(g)$ is calculated concretely.

According to the Siegel maximal parabolic subgroup $P_2$, $G$ has the Bruhat decomposition $G = \coprod_{i=0}^{2} P_2 w_i P_2$, where

$$(2.16) \quad w_0 = 1_4, \quad w_1 = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix} \quad \text{and} \quad w_2 = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$$

be its Weyl group elements. It is well known that for any Weyl group element $w_i$, one has the decomposition for the unipotent subgroup of $G$ such that $N_2 = N^{w_0} \cdot N_{w_i}$, where

$$(2.17) \quad N^{w_0} = N_2, \quad N^{w_1} = \left\{ n(x) \mid x = \begin{pmatrix} x_1 & x_2 \\ x_2 & 0 \end{pmatrix} \right\} \quad \text{and} \quad N^{w_2} = \{1_4\}$$

and

$$(2.18) \quad N_{w_0} = \{1_4\}, \quad N_{w_1} = \left\{ n(x) \mid x = \begin{pmatrix} 0 & 0 \\ 0 & x_3 \end{pmatrix} \right\} \quad \text{and} \quad N_{w_2} = N_2.$$
**Lemma 1.** Let $E_{S,T}(g)$ be the Fourier coefficients of the Fourier expansion of the minimal parabolic Eisenstein series formulated in (2.15). For all $S \in S_{\infty}^\sim$ and $T \in M_0^\sim(S)$, it is expressed as follows.

$$E_{S,T}(g) = \sum_{i=0}^{2} \sum_{\gamma \in Q_i \setminus M_2} \int_{N_{w_i} \setminus N_{w_i}(\mathbb{A})} e(-\sigma(S\gamma^{-1}x\gamma))dn(x)$$

$$\times \int_{N_{w_i}(\mathbb{A})} \varphi_{\lambda+\rho}^{(2)}(s, w_i n(x) \gamma m ((a_1 \ a_2 u)), s)$$

$$\times e(-\sigma(S\gamma^{-1}x\gamma))dn(x),$$

(2.19)

where $Q_i$ be the subgroup of $M_2$ defined by

$$Q_0 = M_2, \quad Q_1 = \left\{ m(a) \mid a = \begin{pmatrix} a_1 & b \\ 0 & a_2 \end{pmatrix} \in GL(2) \right\} \quad \text{and} \quad Q_2 = M_2.$$

**Proof.** It is easy to check that $w_i^{-1}P_2w_i \cap P_2 = N_{w_i}Q_i$ for all $i = 0, 1$ and 2. The coset $w_i^{-1}P_2w_i \cap P_2 \setminus P_2$ is equivalent to the set $\{nm \mid n \in N_{w_i}, \ m \in Q_i \setminus M\}$. This equivalence relation will be acquired by computing the residue class of the coset. Since the map $P \rightarrow Pw_1P, \ p \mapsto w_1p$ is surjective, then we have an isomorphism

$$w_i^{-1}P_2w_i \cap P_2 \setminus P_2 \cong P_2 \setminus P_2w_iP_2 \cong \{nm \mid n \in N_{w_i}, \ m \in Q_i \setminus M\}.$$

The Fourier coefficient $E_{S,T}(g)$ is as follows when the sum running $\gamma$ is rewritten using the isomorphism.

$$E_{S,T}(g) = \sum_{i=0}^{2} \int_{N_2 \setminus N_2(\mathbb{A})} \int_{N_{w_i} \setminus N_{w_i}(\mathbb{A})} \phi_{\lambda+\rho}^{(2)}(s, \gamma g)e(\gamma g, s)e(-\sigma(Sx))dn(x)$$

$$\times \int_{N_{w_i}(\mathbb{A})} \varphi_{\lambda+\rho}^{(2)}(s, \delta \gamma g)e(\delta \gamma g, s)e(-\sigma(Sx))dn(x).$$

For the element in $N_2(\mathbb{A})$, transformation of variable $n(x)$ to $\gamma^{-1}n(x)\gamma$ shows that

$$E_{S,T}(g) = \sum_{i=0}^{2} \sum_{\gamma \in Q_i \setminus M_2} \int_{N_{w_i} \setminus N_{w_i}(\mathbb{A})} \varphi_{\lambda+\rho}^{(2)}(s, w_i n(x) \gamma m ((a_1 \ a_2 u)))$$

$$\times e(w_i n(x) \gamma m ((a_1 \ a_2 u)), s)e(-\sigma(S\gamma^{-1}x\gamma))dn(x).$$

Because of $N_2(\mathbb{A}) = N_{w_i}(\mathbb{A}) \cdot N_{w_i}(\mathbb{A})$, we obtain the statement. □

The next opinion is obtained because we classify the Fourier coefficient $E_{S,T}(g)$ according to the rank of $S \in S_{\infty}^\sim$ concretely using Lemma 1.

**Proposition 3.** The assumption and notation are same as in Lemma 1. The Fourier coefficient $E_{S,T}(g)$ can be described concretely as follows.
(i) If $S = 0_2$, then we have

\begin{equation}
(2.21) \quad \varphi^{(2)}_{\lambda + \rho}(s, m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) \\
+ \int_{N_{w_1}(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_1 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(w_1 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) dn(x) \\
+ \sum_{l \in \mathbb{Q}} \int_{N_{w_1}(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_1 n(x) m \left( \begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+l) \end{array} \right)) \\
\times \nu(w_1 n(x) m \left( \begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+l) \end{array} \right), s) dn(x) \\
+ \int_{N_2(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) dn(x).
\end{equation}

(ii-1) If rank $S = 1$ and $S = \left( \begin{array}{c} s_1 \\ s_2 \\ s_3 \end{array} \right)$ such that $s_2 = s_3 = 0$ or $s_1 s_3 = s_2^2$, then we have

\begin{equation}
(2.22) \quad \int_{N_2(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) e(-\sigma(Sx)) dn(x) \\
+ \int_{N_{w_1}(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_1 n \left( \begin{array}{cc} 0 & 0 \\ 0 & x_3 \end{array} \right) m \left( \begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+x_2/s_1) \end{array} \right)) \\
\times \nu(w_1 n \left( \begin{array}{cc} 0 & 0 \\ 0 & x_3 \end{array} \right) m \left( \begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+x_2/s_1) \end{array} \right), s) e(-s_1 x_3) dx_3.
\end{equation}

(ii-2) If rank $S = 1$ and $S = \left( \begin{array}{c} 0 \\ 0 \\ s_3 \end{array} \right)$, then we have

\begin{equation}
(2.23) \quad \int_{N_2(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) e(-\sigma(Sx)) dn(x) \\
+ \int_{N_{w_1}(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_1 n \left( \begin{array}{cc} 0 & 0 \\ 0 & x_3 \end{array} \right) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \\
\times \nu(w_1 n \left( \begin{array}{cc} 0 & 0 \\ 0 & x_3 \end{array} \right) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) e(-s_3 x_3) dx_3.
\end{equation}

(iii) If rank $S = 2$, then we have

\begin{equation}
(2.24) \quad \int_{N_2(A)} \varphi^{(2)}_{\lambda + \rho}(s, w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)) \nu(w_2 n(x) m \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right), s) e(-\sigma(Sx)) dn(x).
\end{equation}

In the above proposition, what is necessary is to give the Iwasawa decomposition of $w_1 n(x) m(a)$ for $a = \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)$ or $a = \left( \begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+a) \end{array} \right)$, because the domain on the Eisenstein series $\varepsilon(g, s)$ is depend only on the diagonal block of $P_2 \subset G$ which was explain in Theorem 1. If we compute the Iwasawa decomposition, in all cases, $\tilde{f}^{-1}(w_1 n(x) m(a)) = \left( \begin{array}{cc} a_1 & a_2 \\ 0 & a_2 \end{array} \right)$ for $\tilde{f}$ in Theorem 1.
Theorem 3. Let $E(g, s)$ be the Eisenstein series of weight $k \in 2\mathbb{Z}$ with respect to the minimal parabolic subgroup $P$ of $G$. We put $g = m(a)$ for $a = \left( \begin{smallmatrix} a_1 & a_2 \\ 0 & a_2 \end{smallmatrix} \right) \in \text{GL}(2)$. The imaginary part of the action of $\sqrt{-1}$ multiple of the unit matrix of degree 2 on $G$ is defined by $y$, that is $y = a'a$. We also define the imaginary part of the action of $a$ on $\sqrt{-1}$ as $v$ and $\tau = u + \sqrt{-1}v$. Using the notation $\xi(s) = \pi^{-s/2}\Gamma(s/2)\zeta(s)$ and the Pochhammer symbol $(a)_i = \Gamma(a+i)/\Gamma(a)$, for all $n(x) \in N_2$, the Fourier expansion of the normalised minimal parabolic Eisenstein series

\begin{equation}
E^*(n(x)g, s) = \varepsilon^*(n(x)g, s)E_2^*(n(x)g, s)
= \xi(s)(2s-2)(s/2)\left( (s-1)/2 \right) (s-1,k)\varepsilon(n(x)g, s-k)E(n(x)g, s-k)
\end{equation}

along $P$ is given as following.

First, we show the Fourier expansion of the normalised Eisenstein series

\begin{equation}
E^*(n(x)g, s) = \xi(2s-2)(s-1,k)\varepsilon(n(x)g, s)
\end{equation}

such that

\begin{equation}
E^*(n(x)g, s) = \delta(y)^{\frac{1}{2}}v^{\frac{1}{2}} - k \left\{ \delta(y)^{-1}v^s\xi(2s-2)(s-1,k) + v^{-s+1}\xi(2s-3)(s-k-1,k)
+ \sum_{m=1}^{\infty} m^{-s+1}\sigma_{2s-3}(m)W_{-k,s-\frac{1}{2}}(4\pi mv)e(m\tau)
+ (s-k-1,k)(s-1,k)\sum_{m=1}^{\infty} m^{-s+1}\sigma_{2s-3}(m)W_{k,s-\frac{3}{2}}(4\pi mv)e(-m\tau) \right\},
\end{equation}

where $\sigma_s(n)$ is a divisor sum defined by $\sigma_s(n) = \sum_{d|n} d^s$ and $W_{\nu, \mu}(z)$ is a Whittaker function which is given by the integral

\begin{equation}
W_{\nu, \mu}(z) = \frac{e^{-z/2}z^{\nu+1/2}}{\Gamma(-\nu + \mu + 1/2)} \int_0^\infty e^{-tz}t^{-\nu-1/2}(1 + t)^{\nu-1/2}dt,
\end{equation}

for $\text{Re} (-\nu + \mu + 1/2) > 0$ and $\text{Re} z > 0$.

Second, we show the Fourier expansion of the normalised Siegel-Eisenstein series

\begin{equation}
E_2^*(n(x)g, s) = (s/2)_{k/2}(s-1/2)_k\xi(s)(2s-2)E(n(x)g, s-k)
\end{equation}

such that

\begin{equation}
E_2^*(g, s) = \varepsilon_2(g, s) + \delta(y)^{\frac{3-s-k}{2}}v^{\frac{1}{2}}2^{-k}(s-1,k)\xi(s)(2s-2)
+ \delta(y)^{\frac{3-s-k}{2}}v^{\frac{1}{2}}2^{-k}(s-k-1,k)\xi(s-2)(2s-3)
+ 2v^{\frac{1}{2}}\sum_{\delta(S) = 0, S \neq 0_2}^\delta(S) > 0 \left\{ \delta(y)^{\frac{s-k}{2}}|\sigma(Sy)|^{-\frac{s}{2}}\xi(2s-2)F_{e(S)}^{(1)}(2-s) \right\}
\end{equation}
\[
\times \left( \frac{3 - s - k}{2} \right) \frac{W_{\frac{3 - s - k}{2}}}{2} (4\pi|\sigma(Sy)|) \\
+ \delta(y)^{\frac{3 - s - k}{2} - k|\sigma(Sy)|} |\sigma(Sy)|^{\frac{s - 3}{2}} \xi(2s - 3) F^{(1)}_{e(S)}(s - 1) \\
\times \left( \frac{s - k}{2} \right) \frac{W_{\frac{s - k}{2}}}{2} (4\pi|\sigma(Sy)|) \right) e(\sigma(Sx)) \\
+ 2^{1 - 2k} y^{\frac{1}{2} - k} \sum_{\delta(S) = 0, S \neq 0} \left\{ \delta(y)^{\frac{3 - s - k}{2} |\sigma(Sy)|} |\sigma(Sy)|^{\frac{s - 3}{2}} \xi(2s - 2) F^{(1)}_{e(S)}(2 - s) \\
\times \left( \frac{3 - s - k}{2} \right) \frac{W_{\frac{3 - s - k}{2}}}{2} (4\pi|\sigma(Sy)|) \\
+ \delta(y)^{\frac{3 - s - k}{2} |\sigma(Sy)|} |\sigma(Sy)|^{\frac{s - 3}{2}} \xi(2s - 3) F^{(1)}_{e(S)}(s - 1) \\
\times \left( \frac{s - k}{2} \right) \frac{W_{\frac{s - k}{2}}}{2} (4\pi|\sigma(Sy)|) \right) e(\sigma(Sx)) \\
+ 2^{3} \pi^{- \frac{1}{4}} y^{\frac{1}{2}} \left\{ \sum_{\delta(S) > 0} (2\pi)^{-k} (2\sigma(2S))^{\frac{s - k - 3}{2}} L^*(s - 1, \chi) F^{(2)}_{S}(s) \\
\times (s - k - 1)_{2k} \omega \left( 2\pi y, S; \frac{s + k}{2}, \frac{s - k}{2} \right) e(\sigma(Sy)) \\
+ \sum_{\delta(S) > 0} (2\pi)^{-k} (2\sigma(2S))^{\frac{s - k - 3}{2}} (2\sigma(2S))^{\frac{s - k - 3}{2}} L^*(s - 1, \chi) F^{(2)}_{S}(s) \\
\times (s - k - 1)_{2k} \omega \left( 2\pi y, S; \frac{s + k}{2}, \frac{s - k}{2} \right) e(\sigma(Sy)) \\
+ \sum_{\delta(S) < 0} (\delta(y))^{\frac{k}{2}} (-2\sigma(2S))^{\frac{s - 3}{2}} L^*(s - 1, \chi) F^{(2)}_{S}(s) \\
\times \left( \frac{s - k}{2} \right) \frac{W_{\frac{s - k}{2}}}{2} (4\pi|\sigma(Sy)|) \right) \},
\]

where \( \varepsilon_{2}(g, s) \) is the Eisenstein series on \( GL(2) \), its flat section is in \( Ind(\cdot | \cdot^{s-1/2}, | \cdot |^{5/2-s}) \) and \( e(S) = \gcd(S) \). Here the definition of some functions remarked. For \( s \in \mathbb{C} \) and \( S \in \mathcal{S}_{2, \sim} \),

\[(2.31) \quad F^{(1)}_{e(S)}(s) = \prod_{p \mid e(S)} F^{(1)}_{p}(e(S), s), \quad F^{(1)}_{p}(e(S), s) = \sum_{i=0}^{\text{ord}_p e(S)} p^{-(s-1)i} \]

and

\[(2.32) \quad F^{(2)}_{S}(s) = \prod_{p \mid f} F^{(2)}_{p}(S, s), \]

\[F^{(2)}_{p}(S, s) = \sum_{i=0}^{\alpha_1} p^{i(2-s)} \left( \sum_{m=0}^{\alpha_i - 1} p^{m(3-2s)} - \chi(p)p^{1-s} \sum_{j=0}^{\alpha_i - 1} p^{j(3-2s)} \right). \]
Here we note that \(-\delta(2S) = D(S)f^2\) for the fundamental discriminant \(D(S)\) and \(f \in \mathbb{Z}^\ast\), \(\alpha_1 = \text{ord}_p e(S), \alpha = \text{ord}_p f\) and the Kronecker symbol \(\chi(\cdot) = \left(\frac{D(S)}{\cdot}\right)\). We put \(L(s, \chi)\) the Dirichlet’s \(L\)-function of \(\chi\) normalised by \(\pi^{-s/2}\Gamma(s/2)L(s, \chi) = L^\ast(s, \chi)\) and \(\omega(y, S, \alpha, \beta)\) the confluent hypergeometric function as the same notation in [Sh].

The minimal parabolic Eisenstein series converges for \(\text{Re } s > 3\), but can be analytically continued on the whole of the complex plane as a meromorphic function of \(s\). It satisfies a functional equation \(s \rightarrow 3 - s\) and has simple poles at \(s = 1\) and \(2\).

Proof. In Proposition 3, if we calculate the Iwasawa \(A\)-part of the restriction for \(P_2\) of \(w_1n(x)m(a)\) for \(i = 1\) or \(2\) and for \(a = \left(\begin{array}{cc} a_1 & a_2u \\ 0 & a_2 \end{array}\right)\) or \(\left(\begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+a) \end{array}\right)\), it is understand that all of it is not depend on \(N_i(A)\) and explicitly given by \(\left(\begin{array}{cc} a_1 & a_2u \\ 0 & a_2 \end{array}\right)\). Then the local integrals (ii-1), (ii-2) and (iii) of Proposition 3 come down \(\varepsilon(m(a), s)\) for \(a = \left(\begin{array}{cc} a_1 & a_2u \\ 0 & a_2 \end{array}\right)\) multiple of the integral of the flat section \(\varphi_{\chi+\rho}^{(2)}\) of the Siegel-Eisenstein series \(E_2\), \(s, \chi\) and \(e(\sigma(Sx))\) on \(N_{w_1}(\mathbb{A})\). The Fourier expansion of \(E_2\) was considered by S. Mizumoto in [M] and Y. Hasegawa and T. Miyazaki in [HM]. Using the reference and Shimura’s explicit expression of the confluent hypergeometric functions in [Sh] and considering the shift of \(\rho\), we get the formula (2.30). Especially, the local integrals of the second term and the third term of (i) in Proposition 3 are calculated by

\[
\varepsilon(m(a), s) \times \left\{ \int_{N_{w_1}(\mathbb{A})} \varphi_{\chi+\rho}^{(2)}(s, w_1n(x))dn(x) + \sum_{l \in \mathbb{Q}} \int_{N_{w_1}(\mathbb{A})} \varphi_{\chi+\rho}^{(2)}(s, w_1n(x)m\left(\left(\begin{array}{cc} 0 & a_2 \\ a_1 & a_2(u+l) \end{array}\right)\right))dn(x) \right\}
\]

\[
= \varepsilon(m(a), s) \times \sum_{\gamma \in \mathbb{B} \backslash \text{GL}(2)} \int_{N_{w_1}(\mathbb{A})} \varphi_{\chi+\rho}^{(2)}(s, \gamma m(a))dn(x).
\]

Since the integral sets a flat section of the induced representation \(\text{Ind}_{\mathbb{B}}^{\text{GL}(2)}(\cdot|s-\frac{3}{2}|_{\mathbb{A}}^{-1} \cdot |\frac{5}{2} - \cdot|_{\mathbb{A}}^{-s})\), so that the summation is equal to the Eisenstein series on \(\text{GL}(2)\). In the well-known formula of the Fourier expansion of the Eisenstein series on \(\text{GL}(2)\), we add to the shift of \(\rho\).

The functional equation follows from the local functional equations such that \(\xi(s) = \xi(1 - s), (-s)^n = (-1)^n(s - n + 1)_n, F_{b}^{(1)}(s) = b^{1-s}F_{b}^{(1)}(1-s), F_{s}^{(2)} = f^{3-2s}F_{s}^{(1)}(3-s), \sigma_s(n) = |n|^s\sigma_{-s}(n), L^\ast(s, \chi) = | - \delta(2S)/f^2|^{\frac{1}{2}-s}L^\ast(1-s, \chi), W_{\nu, \mu}(z) = W_{\nu, -\mu}(z)\) and \(\omega(y, S; \alpha, \beta) = \omega(y, S; 3 - \alpha, 3 - \beta)\). If we exchange \(s\) to \(3 - s\) in (2.30), then the first term itself, the second term and the third term, the forth term and the fifth term, the sixth term and the seventh term, the eighth term and the ninth term respectively have equality.

Since the function \(\xi(s)\) has poles \(-1/2\) at \(s = 0\) and \(1\) at \(s = 1\), then \(E_2^\ast(g, s)\) has simple poles at \(s = 1\) and \(2\).

Since the Fourier expansion of the minimal parabolic Eisenstein series was written exactly, then the analytical properties of the Eisenstein series came to be found well.
3. Jacquet-Shalika integrals and critical values of the exterior square $L$-functions

There is a fundamental problem of Langlands’ theory of automorphic $L$-functions such that every general automorphic $L$-function initially defined as an Euler product in some half-plane, continues to a meromorphic function in all of $s \in \mathbb{C}$, with only finitely many poles, and a functional equation relating its values at $s$ and $1 - s$. It has been successfully attacked in general using two different methods. One of it is the explicit construction of zeta-integrals and the other one is the Langlands-Shahidi method using Eisenstein series and their Fourier coefficients.

According to the previous work of G. Harder in [H], he constructed the cohomology classes in the cohomology groups of arithmetic quotients and provided it with integral over suitable cycle. Then by summing it over the classes in the genus which is called the period integrals, the critical values of $L$-functions attached to algebraic Hecke characters were appeared.

In this section, to refer the way of [GRS], we calculate the $H = \text{GL}(2) \times \text{GL}(2)$-period integral of the residue of the Eisenstein series and it is shown clearly that the critical values of the exterior square $L$-functions appear.

3-1. Eisenstein cohomology on arithmetic quotients of the Siegel upper half space of degree 2.

In the introduction of this paper, we had already reviewed the structures of cohomology groups of $\Gamma \backslash G/K$ for an arithmetic torsion free subgroup $\Gamma \subset G(\mathbb{Z})$. Then we induct the result of J. Schwermer in [Sc], p. 254, about the Eisenstein cohomology classes.

**Proposition 4.** Let $E^*(g, s)$ be the minimal parabolic Eisenstein series of weight 6 which is defined in the previous section. The residue of $E^*(g, s)$ at $s = 1$ is closed and harmonic and represents a non-trivial class in the Eisenstein cohomology of degree 3.

Considering this proposition, we let calculate the period integrals of the residue of $E^*(g, s)$ at $s = 1$ and then obtain the critical values of the exterior square $L$-functions. Since the Fourier expansion of $E^*(g, s)$ was explicitly shown in Theorem 3 (II-2), then the residue of $E^*(g, s)$ at $s = 1$ is clarified by calculating the Laurent expansion at $s - 1$ of zeta function, gamma function, the confluent hypergeometric functions and other special functions appearing in the Fourier expansion of the Eisenstein series.

**Theorem 4.** The notations are same as in Theorem 3. For all $g = m \left( \begin{smallmatrix} a_1 & a_2 \\ 0 & a_2 \end{smallmatrix} \right) \in G$ and $s \in \mathbb{C}$, take $E^*(g, s)$ as the minimal parabolic Eisenstein series of weight $k \in 2\mathbb{Z}$. The residue of $E^*(g, s)$ at $s = 1$ is explicitly given as following. For $k > 0$,

\begin{align}
\text{Res}_{s=1} E^*(g, s) &= \varepsilon(g, 1) \cdot \delta(y)^{-\frac{k}{2}} v^{\frac{1}{2}} \left( \delta(y)^{-\frac{2-k}{6}} \pi \right. \\
&\quad - 2^{-k} \delta(y)^{\frac{1}{2}} \sum_{m=1}^{\infty} \sigma_{-1}(m) W_{-k, \frac{1}{2}}(4\pi mv) e(m\tau) \\
&\quad \left. - 2^2 \pi^{-\frac{1}{2}} \sum_{\delta(S) = -\square < 0} (-\delta(2S))^{-1} (-\delta(2Sy))^{\frac{1}{2}} F_s^{(2)}(1) \left( \frac{1 - k}{2} \right)^{k-\frac{1}{2}} \right)
\end{align}
\[
\times \omega \left( 2\pi y, S; \frac{1+k}{2}, \frac{1-k}{2} \right) e(\sigma(Sy)) \right\}.
\]

For \( k = 0 \),
\[
(3.2)
\]
\[
\text{Res}_{s=1} E^*(g, s) = \varepsilon(g, 1)(\delta(y)v)^{\frac{1}{2}} \left\{ \frac{1}{2} \left( \log \frac{4\pi v}{\delta(y)} + \gamma \right) + 2\log |\eta(\tau)| \right\}
- 2 \sum_{\delta(S)=0, S \neq 0_2} \sigma_0(e(S))K_0(2\pi|\sigma(S)|) e(\sigma(Sx))
- 2 \sum_{\delta(2S)=-\square<0} \sigma_0(e(S))K_0(2\pi\sqrt{\sigma(Sy)^2 - \delta(2Sy)}e(\sigma(Sx)) \right\}.
\]

**Proof.** Since for all \( k \in 2\mathbb{Z} \), the Eisenstein series \( \varepsilon^*(g, s) \) is entire at \( s = 1 \), then it appears the value of \( s = 1 \) in the part of the residue of the minimal parabolic Eisenstein series at \( s = 1 \). On the other hand, the Siegel-Eisenstein series \( E_2(g, s) \) has poles in the first term \( \varepsilon_2(g, s) \), the second term and the last term for the Fourier expansion given in Theorem 3, (2.30) for \( k > 0 \). In this case, the functions \( \xi(s) (\xi(2s - 2)) \) and \( L^*(s - 1, \chi) = (-\delta(2S))^{1/2} f^{-1} L^*(2 - s, \chi) \) have a singularity. We also count a zero of order 1 of functions \( (s - 1)_k \) or \( \frac{(2s - k)}{2} \), (3.1) is obtained.

If \( k = 0 \), the poles of \( E_2(g, s) \) appear in \( \varepsilon_2(g, s) \), the second term, the forth term, the fifth term and the last term. In this case, we remark that
\[
W_{0,0}(4\pi|\sigma(Sy)|) = 2|\sigma(Sy)|^{\frac{1}{2}} K_0(2\pi|\sigma(Sy)|)
\]
and
\[
\omega \left( 2\pi y, S; \frac{1}{2}, \frac{1}{2} \right) = 2^{\frac{1}{2}} \pi^{\frac{1}{2}} (-\delta(Sy))^{\frac{1}{2}} K_0 \left( 2\pi\sqrt{\sigma(Sy)^2 - \delta(2Sy)} \right).
\]

where the relation between the hypergeometric functions, it says more correctly \( W \)-Whittaker function and the confluent hypergeometric function, and \( K \)-Bessel function. \( \Box \)

After this section, computing the period integral of this residue, then we show that the exterior square \( L \)-function is included in the integral.

**3.2. Formulation of the period integrals.**

Let \( H \) denote the subgroup of \( G \) which compose fixed points of an involution \( \theta \) of \( G \) defined over \( \mathbb{Q} \). We called such an \( H \) a symmetric subgroup of \( G \) and the pair \( (G, H) \) a symmetric pair. In this article, we take \( H \) as \( \text{GL}(2) \times \text{GL}(2) \) which embedded in \( G \) by
\[
(3.3)
\left( \begin{array}{cc} a_1 & a_2 \\ a_3 & a_4 \end{array} \right), \left( \begin{array}{cc} b_1 & b_2 \\ b_3 & b_4 \end{array} \right) \mapsto \left( \begin{array}{cc} a_1 & b_1 & a_2 \\ a_3 & -b_3 & a_4 \end{array} \left( \begin{array}{c} a_2 \\ -b_3 \\ a_4 \end{array} \right) \right).
\]

The sublattice \( \Gamma^\vee = H_g(\Gamma \backslash \mathbb{X}, \mathbb{Z}) \subset H^{q-1}(\Gamma \backslash \mathbb{X}, \Omega^q(\Gamma \backslash \mathbb{X}))^\vee \) consists of linear forms on \( H^{q-1}(\Gamma \backslash \mathbb{X}, \Omega^q(\Gamma \backslash \mathbb{X})) \) and these linear forms are natural inner product between \( q \)-cycles \( H(\mathbb{Q}) \backslash H(A) \in \Omega_q(\Gamma \backslash \mathbb{X}) \) and closed \( q \)-forms \( f \in \Omega^q(\Gamma \backslash \mathbb{X}) \) as follows.
\[
(3.4)
\left( H(\mathbb{Q}) \backslash H(A), f \right) = \int_{H(\mathbb{Q}) \backslash H(A)} f(h) dh.
\]
The Stokes theorem says that the pairing is independent of the choice of representatives of the equivalence classes \( H_q(\Gamma \setminus \mathcal{X}, \mathbb{C}) \) and \( H^q(\Gamma \setminus \mathcal{X}, \mathbb{C}) \) and defines a pairing between them. We call the pairing a period integral. We want to give an explicit expression for that period integral.

3-3. Calculation of the period integrals of the Eisenstein cohomology classes.

If we refer to the calculation method of the article [GRS], applying the truncation operator to \( E^*(g, s) \) and computing its integrals follow our main theorem.

**Theorem 5.** Let \((\pi, V_\pi)\) be the cuspidal representation of \( \text{GL}(2) \). We define \( \Omega_{\psi}^{(2)} \) the period attached to a flat section \( \psi^{(2)} \in V_\pi \) appearing in the minimal parabolic Eisenstein series \( E^*(g, s) \). Then the integral over \( H(\mathbb{Q}) \setminus H(\mathbb{A}) \) for \( H = \text{GL}(2) \times \text{GL}(2) \) of the residue of the minimal parabolic Eisenstein series at \( s = 1 \) expressed as following.

\[
\Omega_{\psi}^{(2)} \cdot \int_{H(\mathbb{Q}) \setminus H(\mathbb{A})} \text{Res}_{s=1} E^*(h, s) dh = L(1/2, \pi)L(1, \pi, \wedge^2).
\]

Here \( L(1/2, \pi) \) be the special value of the standard \( L \)-function of \( \pi \).

Since we prove this main theorem, following result by D. Bump and S. Friedberg in [BF] such that the Rankin-Selberg integral which have been discovered involve Eisenstein series represents a product of two \( L \)-functions is useful.

**Lemma 2.** Let \( \varepsilon(g, s) \) be an Eisenstein series on \( \text{GL}(2) \). For all cusp form \( \varphi \in V_\pi \) and \( \alpha \in \mathbb{C} \), we have

\[
L(1/2, \pi)L(s, \pi, \wedge^2) = \int_{\text{GL}(2, \mathbb{Q}) \setminus \text{GL}(2, \mathbb{A})} \varphi\left( \alpha, \left( g^{\gamma g^{-1}} \right) \right) \varepsilon(g, s) dg.
\]
Lemma 3. If $\text{Re } s$ is sufficiently large, then the following formulae are valid with a certain choice of measures. For $\alpha \in \mathbb{C}$, we have

$$(3.8) \int_{H(\mathbb{Q}) \backslash H(\mathbb{A})} \text{Res}_{s=1} E^*(h,s) dh = \int_{K_H} \int_{\text{GL}(2,\mathbb{Q}) \backslash \text{GL}(2,\mathbb{A})} \varphi \left( \alpha, \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right) dk,$$

where $K_H$ is the maximal compact subgroup of $H$.

Using the above two lemmas, we prove our main theorem.

Proof. Since the minimal parabolic subgroup $E^*(g,s)$ is decomposed as in Theorem 1, then the integrand is decomposed by

$$\varphi \left( \alpha, \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right) = \varphi^{(2)} \left( \alpha, \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right).$$

The property of $\varphi^{(2)}$ says that it can be separated by $\varphi^{(2)} \left( \alpha, \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right) \varphi^{(2)}(\alpha, k)$ and the Eisenstein series on $\text{GL}(2)$ is not depend on $k \in K$. Then the integral in Lemma 2 is equal to

$$\int_{H(\mathbb{Q}) \backslash H(\mathbb{A})} \text{Res}_{s=1} E^*(h,s) dh = \Omega^{-1}_{\varphi^{(2)}} \cdot \int_{\text{GL}(2,\mathbb{Q}) \backslash \text{GL}(2,\mathbb{A})} \varphi^{(2)} \left( \alpha, \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right) \varepsilon \left( \left( \begin{smallmatrix} g & \ast \\ \ast & 1 \end{smallmatrix} \right) \right),$$

where $\Omega^{-1}_{\varphi^{(2)}}$ means the period attached to $\varphi^{(2)}$. Since this integral is exactly the special value of the Rankin-Selberg integral at $s = 1$ which is found by Bump and Friedberg in Lemma 2 up to the multiple by $\Omega_{\varphi^{(2)}}$, we obtain our main theorem. □

Since the analytics of $L(1, \pi, \wedge^2)$ follows from that of $\text{Res}_{s=1} E^*(g,s)$ referring to our main theorem, then it becomes now easily to prove the Deligne’s conjecture on $L(1, \pi, \wedge^2)$.
