ABSTRACT. -Let a be a non-isolated point of a topological space S and $X^0 = (X_t^0, 0 \le t < \zeta^0, P_x^0)$ be a symmetric diffusion on $S_0 = S \setminus \{a\}$ such that $P_x^0(\zeta^0 < \infty, X_{\zeta^0-}^0 = a) > 0, x \in S_0$. By making use of Poisson point processes taking values in the spaces of excursions around a whose characteristic measures are uniquely determined by X^0, we construct a symmetric diffusion $\tilde{X}$ on S with no killing inside S which extends X^0 on S_0. We also prove that such a process $\tilde{X}$ is unique in law and its resolvent and Dirichlet form admit explicit expressions in terms of X^0.

Keywords: symmetric diffusion, Poisson point process, excursions, entrance law, energy functional, Dirichlet form

1 Introduction

Let S be a locally compact separable metric space and a be a non-isolated point of S. We put $S_0 = S \setminus \{a\}$. The one point compactification of S is denoted by S_Δ. When S is compact already, Δ is added as an isolated point. Let m be a positive Radon measure on S_0 with $\mathrm{Supp}[m] = S_0$. m is extended to S by setting $m(\{a\}) = 0$.

We assume that we are given an m-symmetric diffusion $X^0 = (X_t^0, P_x^0)$ on S_0 with life time ζ^0 satisfying the following four conditions:

A.1 $\quad P_x^0(\zeta^0 < \infty,\ X_{\zeta^0-}^0 \in \{a\} \cup \{\Delta\}) = P_x^0(\zeta^0 < \infty), \quad \forall x \in S_0.$

We define the functions $\varphi(x),\ u_\alpha(x),\ \alpha > 0$, of $x \in S_0$ by

$$\varphi(x) = P_x^0(\zeta^0 < \infty,\ X_{\zeta^0-}^0 = a), \quad u_\alpha(x) = E_x^0(e^{-\alpha\zeta^0}; X_{\zeta^0-}^0 = a).$$

A.2 $\quad \varphi(x) > 0, \qquad \forall x \in S_0,$

A.3 $\quad u_\alpha \in L^1(S_0; m), \qquad \forall \alpha > 0.$

A.4 $\quad u_\alpha \in C_b(S_0), \qquad G_\alpha^0(C_b(S_0)) \subset C_b(S_0), \qquad \alpha > 0,$

where G_α^0 is the resolvent of X^0 and $C_b(S_0)$ is the space of all bounded continuous functions on S_0.

By making use of excursion-valued Poisson point processes whose characteristic measures are uniquely determined by X^0, or to be a little more precise, by piecing together those excursions which start from a and return to a and then possibly by adding the last one that never returns to a, we shall construct in §4 of the present paper a process $\tilde{X}$ on S satisfying

(1) $\tilde{X}$ is an m-symmetric diffusion process on S with no killing inside S,

(2) $\tilde{X}$ is an extension of X^0: the process on S_0 obtained from $\tilde{X}$ by killing upon the hitting time of a is identical in law with X^0.

We call a process $\tilde{X}$ on S satisfying **(1),(2)** a *symmetric extension of* X^0.

We shall also prove in §5 that, under conditions **A.1, A.2** for the given m-symmetric diffusion X^0 on S_0, its symmetric extension is unique in law, satisfies condition **A.3** automatically and admits the resolvent expressible as

$$G_\alpha f(x) = G_\alpha^0 f(x) + u_\alpha(x) \cdot G_\alpha f(a),\ x \in S_0, \quad G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi)},$$

where $(\cdot, \cdot)$ denotes the inner product in $L^2(S_0; m)$ and $L(m_0, \psi)$ is the energy functional in Meyer's sense [21] of the X^0-excessive measure $m_0 = \varphi \cdot m$ and X^0-excessive function $\psi = 1 - \varphi$.

Furthermore the associated Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(S; m)$ will be seen in §5 to have the following simple expression; if we donote by $\mathcal{F}_e$ its extended Dirichlet space, then

$$\mathcal{F}_e = \{w = u_0 + c\varphi : u_0 \in \mathcal{F}_{0,e},\ c \text{ constant}\}, \quad \mathcal{F} = \mathcal{F}_e \cap L^2(S; m),$$
$$\mathcal{E}(w, w) = \mathcal{E}(u_0, u_0) + c^2 \mathcal{E}(\varphi, \varphi),\ \mathcal{E}(\varphi, \varphi) = L(m_0, \psi),$$

where $(\mathcal{F}_{0,e}, \mathcal{E})$ is the extended Dirichlet space for the given diffusion X^0.

In §6, we shall present four examples. Example 6.1 concerns the uniqueness of the symmeric extension of the one dimensional absorbing Brownian motion.

Example 6.2 treats the case where S_0 is a bounded open subset of $\mathbb{R}^d$, $(d \geq 1)$, $S = S_0 \cup \{a\}$ is the one point compactification of S_0 and X^0 is the absorbing Brownian motion on S_0. In this case, $\varphi(x) = 1,\ x \in S_0$. The resulting Dirichlet form on $L^2(S; m)$ (m is the Lebsegue measure on S_0 extended to S by $m(\{a\}) = 0$) is given by

$$\mathcal{F} = \{w = u_0 + c : u_0 \in H_0^1(S_0),\ c \text{ constant}\},$$

$$\mathcal{E}(w, w) = \frac{1}{2} \int_{S_0} |\nabla u_0|^2(x) dx,$$

which is easily seen to be regular, strongly local and irreducible recurrent. A more general Dirichlet form of this type will be presented in §3.2. This type of Dirichlet form first appeared in the paper [8] by the first author and it is recently utilized in a study of the asymptotics of the spectral gap for one parameter family of energy forms([17]). Our study is motivated by a wish to conceive a clearer picture of the sample path of the diffusion on S associated with such a Dirichlet form.

Example 6.3 is essentially one-dimensional, where we shall see that the conditions **A.2** and **A.3** are satisfied if and only if the boundary is regular in Feller's sense. This example is reminiscent of an example by N. Ikeda and S. Watanabe[14].

Example 6.4 is higher dimensional, where the Dirichlet form associated with the constructed process $\tilde{X}$ may not be regular.

In order to identify right quantities to describe the excursion-valued Poisson point processes to be constructed in §4, we shall study in §2 and §3 a strongly local regular Dirichlet form on $L^2(S;m)$ for which the point $\{a\}$ has a positive capacity. In particular, we shall find that the Dirichlet form and the associated resolvent admit exactly the above mentioned expressions. Furthermore, we shall see that the entrance law $\{\mu_t\}$ governing the excursion law ought to be determined by

$$m_0 = \int_0^\infty \mu_t dt,$$

an equation investigated by E.B.Dynkin, R.K.Getoor, P.J.Fitzsimmons and others ([11]).

In a seminal work [15], K.Itô considered a standard process X on S for which a point a is regular for itself. A Poisson point process $\mathbf{Y}$ taking value in the space of excursions around a was then associated, and it was shown that the stopped process X^0 obtained from X by the hitting time at a and the characteristic measure of $\mathbf{Y}$ together determine the law of X uniquely. It was implicitly assumed in [15] that the point a is recurrent in the sense that

$$\varphi(x) = P_x(\sigma_a < \infty) = 1,\ x \in S, \quad \sigma_a = \inf\{t > 0 : X_t = a\}.$$

But, as was shown in P.A. Meyer [20], an *absorbed* Poisson point process can be still associated with X when $\{a\}$ is non-recurrent. See Remark 4.2 in this regard.

Since our present assumption on X^0 requires φ only to be positive, we must handle not only returning excursions from the point a but also non-returning excursions. By restricting ourselves to the case that both X^0 and $\tilde{X}$ are symmetric diffusions however, we shall see that the characteristic measures on these different type of excursion spaces are uniquely determined by X^0 so that, starting with X^0, we can give an explicit construction of $\tilde{X}$.

The Dirichlet form $(\mathcal{E},\mathcal{F})$ on $L^2(S;m)$ associated with a symmetric extension $\tilde{X}$ of X^0 may not be regular but it is quasi-regular in the sense of [19]. Accordingly we can make use of the quasi-homeomorphism in [3] to connect $\tilde{X}$ with the regular Dirichlet form studied in §2, yielding the uniqueness of $\tilde{X}$ and the explicit expression of $(\mathcal{E},\mathcal{F})$.

There are quite a few works [1], [24], [25], [26] dealing with generalizations of Itô's one [15]. See Remark 2.2 and Remark 4.1 in these regards. But construction and uniqueness of a symmetric extension X of a symmetric X^0 as are formulated in the present paper have never been considered.

2 Strongly local Dirichlet form with a point of positive capacity

2.1 Description of the form and resolvent by absorbed process

Let S be a locally compact separable metric space and a be a non-isolated point of S. We denote the complementary set $S \setminus \{a\}$ by S_0. Let m be a positive Radon measure on S with $\mathrm{Supp}[m] = S$ and with $m(\{a\}) = 0$. The inner product in each of the spaces $L^2(S;m),\ L^2(S_0,m)$ will be designated by $(\cdot,\cdot)$.

A Dirichlet form $(\mathcal{E},\mathcal{F})$ on $L^2(S;m)$ is called *regular* if $\mathcal{F} \cap C_0(S)$ is $\mathcal{E}_1$-dense in $\mathcal{F}$ and uniformly dense in $C_0(S)$, where $C_0(S)$ denotes the space of continuous functions on

S with compact support. It is called *strongly local* if $\mathcal{E}(u,v)$ vanishes whenever $u,v \in \mathcal{F}$, Supp$[u]$, Supp$[v]$ are compact and v is constant on a negibourhood of Supp$[u]$, where Supp$[u]$ denotes the topological support of the measure $u \cdot m$. For the sake of a use in §3.2, we make here a remark:

Remark 2.1. If a Dirichlet form $(\mathcal{E},\mathcal{F})$ on $L^2(S;m)$ is regular and strongly local, then the strong locality stated above holds without assuming that Supp$[v]$ is compact. Indeed, assuming the boundedness of v, take a function $w \in \mathcal{F} \cap C_0(S)$ with $w = 1$ on a neighbourhood of $K = \text{Supp}[u]$ and put $v_1 = v \cdot w,\ v_0 = v - v_1$. Then $\mathcal{E}(u,v_1) = 0$. Since v_0 belongs to the part $\mathcal{F}_G$ of $(\mathcal{E},\mathcal{F})$ on the open set $G = S \setminus K$ and $(\mathcal{E},\mathcal{F}_G)$ is a regular Dirichlet form on $L^2(G;m)$ (cf.[9, Th.4.4.3]), we can find $v_n \in \mathcal{F} \cap C_0(G)$ which are $\mathcal{E}_1$-convergent to v_0. Hence $\mathcal{E}(u,v_0) = \lim_{n\to\infty} \mathcal{E}(u,v_n) = 0$ and $\mathcal{E}(u,v) = 0$.

We consider a strongly local regular Dirichlet form $(\mathcal{E},\mathcal{F})$ on $L^2(S;m)$ and an associated m-symmetric Hunt process $X = (X_t, P_x)$ on S. In view of [9, The.4.5.3], X can then be taken to be a diffusion on S_Δ in the sense that all sample paths are continuous functions from $[0,\infty)$ to S_Δ, where S_Δ is the one-point compactification of S when S is non-compact and Δ is an extra point isolated from S when S is compact. In either case Δ will be the cemetery of the sample paths. Furthermore, X can be taken to be of no killing inside S in the sense that

$$P_x(X_{\zeta-} = \Delta, \zeta < \infty) = P_x(\zeta < \infty), \quad x \in S,$$

where $\zeta(\omega)$ denotes the life time, namely, the hitting time of the cemetery Δ of the sample path ω. In particular, when S is compact, $P_x(\zeta = \infty) = 1$ for all $x \in S$.

We make the assumption that

B.1 $\text{Cap}(\{a\}) > 0$.

Here Cap(A) for $A \subset S$ is its 1-capacity relative to $(\mathcal{E},\mathcal{F})$. In what follows, the quasi-continuity of functions on S will be understood with respect to this capacity. Each function $u \in \mathcal{F}$ admits its quasi-continuous version denoted by $\tilde{u}$. 'q.e.' will means 'except for a set of zero capacity'.

The hitting probability and the α-order hitting probability of $\{a\}$ are denoted by φ and u_α respectively:

$$\varphi(x) = P_x(\sigma < \infty), \qquad u_\alpha(x) = E_x(e^{-\alpha\sigma}), \quad x \in S, \tag{2.1}$$

where σ is the hitting time of a by the process X defined by

$$\sigma = \inf\{t > 0 : X_t = a\}. \tag{2.2}$$

The assumption **B.1** implies that u_α is a non-trivial element of $\mathcal{F}$ and it is the α-potential $U_\alpha \nu_\alpha$ of a positive measure ν_α concentrated on $\{a\}$ (cf. [9, §2.2]):

$$\mathcal{E}_\alpha(u_\alpha, v) = \tilde{v}(a)\nu_\alpha(\{a\}) \qquad v \in \mathcal{F}. \tag{2.3}$$

Put

$$\mathcal{F}_0 = \{u \in \mathcal{F} : \tilde{u}(a) = 0\}. \tag{2.4}$$

Then $(\mathcal{E},\mathcal{F}_0)$ is a regular strongly local Dirichlet form on $L^2(S_0;m)$, which is associated with the part $X^0 = (X_t^0, P_x^0)$ of X on the set S_0, namely, the diffusion process X^0

obtained from X by killing upon the hitting time σ (cf. [9, §4.4]). X^0 is of no killing inside S_0 and, if we denote the life time of X^0 by ζ^0, then $\varphi,\ u_\alpha$ admit the expressions

$$\varphi(x) = P^0_x(\zeta^0 < \infty,\ X^0_{\zeta^0-} = a), \quad u_\alpha(x) = E^0_x(e^{-\alpha\zeta^0}; X_{\zeta^0-} = a), \quad x \in S_0, \tag{2.5}$$

in terms of the absorbed process X^0. We further consider the functions

$$\psi^{(1)}(x) = P^0_x(\zeta^0 < \infty,\ X_{\zeta^0-} = \Delta), \quad \psi^{(2)}(x) = P^0_x(\zeta^0 = \infty), \quad x \in S_0, \tag{2.6}$$

and put $\psi = \psi^{(1)} + \psi^{(2)}$ so that $\psi = 1 - \varphi$.

Denote by p_t and G_α the transition function and the resolvent of X respectively. The same notions for the absorbed process X^0 will be denoted by p^0_t and G^0_α. The functions $\varphi,\ \psi^{(1)}, \psi^{(2)}$ on S_0 are X^0-excessive. In particular, $\psi^{(2)}$ is X^0-invariant in the sense that $\psi^{(2)} = p^0_t\psi^{(2)},\ t > 0$. Because of the m-symmetry of X^0, the measure

$$m_0 = \varphi \cdot m \tag{2.7}$$

is an X^0-excessive measure with $m_0 p^0_t = p^0_t\varphi \cdot m$.

Our first aim in this section is to show under the present setting that the form $\mathcal{E}$ as well as the resolvent G_α are uniquely and explicitly determined by quantities depending only on the absorbed process X^0.

We prepare a lemma.

Lemma 2.1. *For an X^0-excessive function v on S_0,*

$$L(m_0, v) = \lim_{t\downarrow 0} \frac{1}{t}\langle m_0 - m_0 p^0_t, v\rangle = \lim_{t\downarrow 0} \frac{1}{t}(\varphi - p^0_t\varphi, v)(\le \infty). \tag{2.8}$$

is well defined as an increasing limit and it holds that

$$L(m_0, v) = \lim_{\alpha\to\infty} \alpha(u_\alpha, v). \tag{2.9}$$

If v is p^0_t-invariant, then for each $t > 0$ and $\alpha > 0$,

$$L(m_0, v) = \frac{1}{t}(\varphi - p^0_t\varphi, v) = \alpha(u_\alpha, v).$$

Proof. If we set $e(t) = (\varphi - p^0_t\varphi, v)$, then

$$e(t+s) = e(t) + (p^0_t\varphi - p^0_{t+s}\varphi, v) = e(t) + (\varphi - p^0_s\varphi, p^0_t v) \le e(t) + e(s),$$

and hence $e(t)/t$ is increasing as t decreases and constant if v is p^0_t-invariant.. We also see that

$$\alpha(u_\alpha, v) = \alpha(\varphi - \alpha G^0_\alpha\varphi, v) = \int_0^\infty e^{-t}(t/\alpha)^{-1}(\varphi - p^0_{t/\alpha}\varphi, v)\ t\ dt$$

increases to $L(v)$ as $\alpha \uparrow \infty$. □

We note that $L(m_0, v)$ is nothing but the *energy functional* of the X^0-excessive measure m_0 and the X^0-excessive function v in the sense of P.A. Meyer [21] when X^0 is transient (cf.[4, §39], [11, p16]). In [4, §39], it is called the mass of v relative to m_0.

Let $\mathcal{F}_e$ (resp.$\mathcal{F}_{0,e}$) be the extended Dirichlet space of $(\mathcal{F},\mathcal{E})$ (resp.$(\mathcal{F}_0,\mathcal{E})$). Each element $u \in \mathcal{F}_e$ admits its quasi continuous version denoted by $\tilde{u}$ again. In view of [9, §4.6], it holds then that

$$\mathcal{F}_{0,e} = \mathcal{F}_{e,0} = \{u \in \mathcal{F}_e : \tilde{u}(a) = 0\},$$

$$\varphi \in \mathcal{F}_e, \qquad \mathcal{E}(\varphi, u) = 0 \quad \forall u \in \mathcal{F}_{e,0}, \tag{2.10}$$

$$\mathcal{F} = \mathcal{F}_e \cap L^2(S;m) \quad \mathcal{F}_0 = \mathcal{F}_{0,e} \cap L^2(S_0, m). \tag{2.11}$$

Furthermore any $w \in \mathcal{F}_e$ can be decomposed as

$$w = u_0 + c\,\varphi, \qquad u_0 \in \mathcal{F}_{e,0}, \quad c \text{ constant} \tag{2.12}$$

and

$$\mathcal{E}(w,w) = \mathcal{E}(u_0,u_0) + c^2\mathcal{E}(\varphi,\varphi). \tag{2.13}$$

Theorem 2.1. (i) *It holds that*

$$\mathcal{E}(\varphi,\varphi) = L(m_0,\psi)(= L(m_0,\psi^{(1)}) + L(m_0,\psi^{(2)})). \tag{2.14}$$

(ii) u_α *is a non-trivial element of* $\mathcal{F} \cap L^1(S_0;m)$.
(iii) *For any* $f \in L^2(S,m)$ *and* $x \in S$,

$$G_\alpha f(x) = G_\alpha^0 f(x) + \frac{(u_\alpha, f)}{\alpha(u_\alpha,\varphi) + L(m_0,\psi)} u_\alpha(x), \quad G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha,\varphi) + L(m_0,\psi)}. \tag{2.15}$$

(iv) *Let* δ_a *be a unit mass concentrated at* $\{a\}$. *Then it is of finite energy integral and its* α*-potential* $U_\alpha\delta_a$ *is related to* u_α *by*

$$\widetilde{U_\alpha\delta_a} = \frac{1}{\alpha(u_\alpha,\varphi) + L(m_0,\psi)} u_\alpha. \tag{2.16}$$

(v) *The point* a *is regular for itself and also an instantaneous state with respect to* X:

$$P_a(\sigma = 0,\ \tau_a = 0) = 1, \qquad \tau_a = \inf\{t > 0 : X_t \in S_0\}. \tag{2.17}$$

Proof. We first give a proof of (ii). According to a general theorem ([9, Chap 4]), the formula obtained by the strong Markov property

$$G_\alpha f(x) = G_\alpha^0 f(x) + u_\alpha(x) G_\alpha f(a) \quad x \in S, \quad f \in L^2(S;m), \tag{2.18}$$

represents the orthogonal decomposition of $G_\alpha f \in \mathcal{F}$ into the space $\mathcal{F}_0$ and its orthogonal complement $\mathcal{H}_\alpha = \{c \cdot u_\alpha : c \text{ constant}\}$ in the Hilbert space $(\mathcal{F}.\mathcal{E}_\alpha)$. We see that $G_\alpha f(a) > 0$ for some $f \in C_0^+(S)$, because otherwise $\mathcal{F} = \mathcal{F}^0$ from (2.18) contradicting to $u_\alpha \in \mathcal{F}$. By (2.18),

$$(u_\alpha, 1) G_\alpha f(a) \le (G_\alpha f, 1) = (f, G_\alpha 1) \le \frac{1}{\alpha}(f,1) < \infty.$$

Next we prove (i) and (iii). For $f \in C_0(S)$, the function $w = G_\alpha f$ has two expressions:

$$w = G_\alpha^0 f + c u_\alpha = u_0 + c\varphi, \quad c = G_\alpha f(a), \quad u_0 \in \mathcal{F}_{e,0}.$$

By [9, Cor.1.6.3, Th.2.1.7], We can find a sequence $\{g_n\}$ of uniformly bounded functions in $\mathcal{F}$ such that

$$\lim_{n\to\infty} g_n = \varphi \ m\text{−a.e.}, \quad \lim_{n\to\infty} \mathcal{E}(g_n - \varphi, g_n - \varphi) = 0.$$

Letting $n \to \infty$ in the equation

$$\mathcal{E}(w, g_n) + \alpha(w, g_n) = (f, g_n),$$

we get

$$c\mathcal{E}(\varphi, \varphi) + c\alpha(u_\alpha, \varphi) = (f, \varphi) - (\alpha G_\alpha^0 f, \varphi).$$

Since the right hand side equals

$$(f, \varphi - \alpha G_\alpha^0 \varphi) = (f, u_\alpha),$$

we arrive at

$$G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + \mathcal{E}(\varphi, \varphi)}, \quad f \in C_0(S). \tag{2.19}$$

(2.19) holds for any bounded Borel f. In particular, we have for any $\alpha > 0$,

$$G_\alpha 1(a) = \frac{(u_\alpha, 1)}{\alpha(u_\alpha, \varphi) + \mathcal{E}(\varphi, \varphi)} \leq \frac{1}{\alpha},$$

and hence

$$\mathcal{E}(\varphi, \varphi) \geq \alpha(u_\alpha, \psi).$$

By letting $\alpha \to \infty$, we get from Lemma 2.1

$$\mathcal{E}(\varphi, \varphi) \geq L(m_0, \psi).$$

In order to prove (2.14), notice that the assumption of the strong locality of $\mathcal{E}$ implies that the killing measure k in the Beurling-Deny representation of $\mathcal{E}$ vanishes (cf. [9, Th.4.5.3]). On account of [9, Lemma 4.5.2],

$$\int_S f^2 dk = \lim_{\alpha\to\infty} \alpha \int_S f(x)^2 (1 - \alpha G_\alpha 1(x)) m(dx), \ f \in \mathcal{F} \cap C_0(S).$$

From (2.18) and (2.19), we have

$$\begin{aligned}
1 - \alpha G_\alpha 1(x) &= 1 - \alpha G_\alpha^0 1(x) - \frac{\alpha(u_\alpha, 1)}{\alpha(u_\alpha, \varphi) + \mathcal{E}(\varphi, \varphi)} u_\alpha(x) \\
&\geq u_\alpha(x) - \frac{\alpha(u_\alpha, 1)}{\alpha(u_\alpha, \varphi) + \mathcal{E}(\varphi, \varphi)} u_\alpha(x) \\
&= \frac{\mathcal{E}(\varphi, \varphi) - \alpha(u_\alpha, \psi)}{\alpha(u_\alpha, \varphi) + \mathcal{E}(\varphi, \varphi)} u_\alpha(x).
\end{aligned}$$

Take $f \in \mathcal{F} \cap C_0(S)$ such that $f(a) \neq 0$. We have from (2.19) and the above inequality

$$\alpha \int_S f^2 (1 - \alpha G_\alpha 1) dm \geq (\mathcal{E}(\varphi, \varphi) - \alpha(u_\alpha, \psi))(\alpha G_\alpha f^2)(a).$$

By letting $\alpha \to \infty$, we get

$$0 \geq (\mathcal{E}(\varphi, \varphi) - L(m_0, \psi))f(a)^2,$$

proving the desired identity (2.14).

Proof of (iv). By (2.3),

$$(u_\alpha, f) = \mathcal{E}_\alpha(u_\alpha, G_\alpha f) = G_\alpha f(a)\nu_\alpha(\{a\}),$$

which combined with (2.15) gives

$$\nu_\alpha = (\alpha(u_\alpha, \varphi) + L(m_0, \psi))\delta_a.$$

Proof of (v). The regularity $P_a(\sigma = 0) = 1$ of the point a for itself follows from **A.1** and a general fact that, for any Borel set B, the set of irregular points $x \in B$ for B is of zero capacity ([9, Chap. 4]). If $P_a(0 < \tau_a < \infty) > 0$, then $P_a(X_{\tau_a} \in S_0 \cup \Delta) = 1$ contradicting the sample continuity and absence of the killing inside S for X. If a were a trap with respect to X, then $G_\alpha f(a) = f(a)/\alpha$ for any $f \in L^2(S; m)$ contradicting (2.15). Accordingly, a is an instantaneous state.

□

Remark 2.2. (i) The present assumptions can be relaxed as follows:
(a) The measure m on S is replaced by $\bar{m} = m + \gamma\delta_a$ for a non-negative constant γ.
(b) $(\mathcal{E}, \mathcal{F})$ is assumed to be a (not necessarily strongly) local regular Dirichlet form on $L^2(S; \bar{m})$, while its part $(\mathcal{E}, \mathcal{F}_0)$ on S_0 is assumed to be a strongly local Dirichlet form on $L^2(S_0; m)$.

Then, in view of the above proof of Theorem 2.1, we readily see that (2.14) and (2.15) remain true under the following modifications:

$$\mathcal{E}(\varphi, \varphi) = L(m_0, \psi) + \delta,$$

$$G_\alpha f(x) = G_\alpha^0 f(x) + \frac{(u_\alpha, f) + \gamma f(a)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi) + \delta + \alpha\gamma} u_\alpha(x),$$

for a non-negative constant δ.

Example 6.1 will indicate stochastic interpretations of the parameters γ and δ.
(ii) The parameters γ, δ have appeared in Rogers' description [24] of the most general extension of a general resolvent G_α^0 under a setting corresponding to $\psi^{(1)} = 0$. Another parameter appearing in [24] is a family of measures $n_\alpha, \alpha > 0$, on S_0, which is reduced to $u_\alpha \cdot m$ under the present symmetry assumption.
(iii) In the setting (i) in the above, G_α is conservative if and only if $\psi^{(1)} = 0$ and $\delta = 0$, and in this case the above expression is reduced to

$$G_\alpha f(x) = G_\alpha^0 f(x) + \frac{(1 - \alpha G_\alpha^0 1, f) + \gamma f(a)}{\alpha(1 - \alpha G_\alpha^0 1, 1) + \alpha\gamma}(1 - \alpha G_\alpha^0 1(x)).$$

Such a formula was found by Y. Le Jan [18](see also [4, §78]) in a general setting to produce conservative resolvents out of a (not necessarily symmetric) submarkovian resolvent and its dual preserving the duality.

2.2 Description of the inverse local time

In §4, we shall construct a diffusion on S with resolvent (2.15) by means of Poisson point processes of excursions, namely, by piecing together the excursions. In this subsection, let us study more about the roles of the measure m_0 and the energy functional $L(m_0, \psi)$ played in the present diffusion X on S.

Let $L(t)$ be the positive continuous additive functional (admitting exceptional set) associated with the smooth measure δ_a (cf.[9, §5.1]):

$$\widetilde{U_\alpha \delta_a}(x) = E_x \left(\int_0^\infty e^{-\alpha t} dL(t) \right) \quad \text{for q.e. } x \in S. \tag{2.20}$$

In particular, (2.20) holds for $x = a$. $L(t)$ is a local time at $\{a\}$ in the sense that it increases only when $X_t = a$:

$$L(t) = \int_0^t I_a(X_s) dL(s).$$

We consider the right continuous inverse $S(t) = \inf\{s : L(s) > t\}$ of $L(t)$.

It is well known that the increasing process $(S(t), P_a)$ is a subordinator killed upon an exponential holding time (cf.[2]). Theorem 2.1 enables us to identify the Lévy measure of the subordinator and the killing rate. Indeed, according to [2, v (3.17)], (2.20) implies the identity

$$E_a(e^{-\alpha S(t)}) = \exp(-t/\widetilde{U_\alpha \delta_a}(a)),$$

which combined with (2.16) leads us to

$$E_a \left(e^{-\alpha S(t)} \right) = e^{-tL(m_0, \psi)} \exp[-t\alpha(u_\alpha, \varphi)]. \tag{2.21}$$

We need a lemma which will play a basic role in §4 again. A family $\{\nu_t\}_{t>0}$ of σ-finite measures on S_0 is called *an X^0-entrance law* if $\nu_t p_s^0 = \nu_{s+t},\ s, t > 0$. Then $\nu_t(f),\ f \in \mathcal{B}^+(S_0)$, is measurable in t and we may let

$$\hat{\nu}_\alpha(f) = \int_0^\infty e^{-\alpha t} \nu_t(f) dt,\ \alpha > 0,\ f \in \mathcal{B}^+(S_0).$$

Lemma 2.2. (i) *There exists a unique X^0-entrance law $\{\mu_t\}$ such that*

$$m_0 = \int_0^\infty \mu_t \ dt. \tag{2.22}$$

(ii) $\qquad \hat{\mu}_\alpha(f) = (u_\alpha, f), \qquad \alpha > 0,\ f \in \mathcal{B}^+(S_0).$
Consequently,

$$\int_0^t \mu_s(f) ds = \int_{S_0} P_x^0(\zeta^0 \le t,\ X_{\zeta^0 -} = a) f(x) m(dx),\ t > 0,\ f \in \mathcal{B}(S_0). \tag{2.23}$$

(iii) $\qquad \mu_t(S_0) < \infty, \quad t > 0.$
(iv) *For any bounded X^0-excessive function v on S_0, $\mu_t(v)$ is right continuous in $t > 0$.*
(v) *For any X^0-excessive function v on S_0, the energy functional $L(m_0, v)$ introduced in Lemma* 2.1 *admits an expression*

$$L(m_0, v) = \lim_{t \downarrow 0} \mu_t(v).$$

When v is p_t^0-invariant, it holds for any $t > 0$ that

$$L(m_0, v) = \mu_t(v).$$

(vi) $L(m_0, \varphi) = \infty$.

Proof. (i) Since

$$p_t^0\varphi(x) = P_x^0(t < \zeta^0 < \infty, X_{\zeta-}^0 = a) \downarrow 0, \quad t \to \infty,$$

$\lim_{t\downarrow 0} m_0 p_t^0(f) = (p_t^0\varphi, f) = 0$ for $f \in L^1(S_0, m)$, namely, m_0 is purely excessive. Hence the desired assertion follows from a well known representation theorem provided that X^0 is transient ([11, Th. 5.25]). But the present situation can be reduced to this case by observing that

$$S_1 = \{x \in S_0 : \varphi(x) > 0\}$$

is a non-trivial X^0-invariant set q.e. and the restriction of X^0 to S_1 is transient (cf. [9, §4.6]).
(ii) For $f \in C_0^+(S_0)$, we have

$$\int_t^\infty \mu_t(f)dt = \int_0^\infty \mu_{t+s}(f)dt = \int_0^\infty \mu_s(p_t^0 f)ds = (\varphi, p_t^0 f),$$

and

$$\mu_t(f) = -\frac{d}{dt}(\varphi, p_t^0 f), \qquad \text{a.e. } t.$$

Hence

$$\begin{aligned} \hat{\mu}_\alpha(f) &= -\int_0^\infty e^{-\alpha t}\frac{d}{dt}(\varphi, p_t^0 f)dt \\ &= \left[-e^{-\alpha t}(\varphi, p_t^0 f)\right]_0^\infty - \alpha\int_0^\infty e^{-\alpha t}(\varphi, p_t^0 f)dt \\ &= (\varphi, f) - \alpha(\varphi, G_\alpha^0 f) = (\varphi - \alpha G_\alpha^0\varphi, f) = (u_\alpha, f). \end{aligned}$$

(iii) By (ii) and Theorem 2.1 (ii), $\hat{\mu}_\alpha(1) = (u_\alpha, 1) < \infty$, from which the desired finiteness follows.
(iv) On account of (iii), we have $\mu_{t+s}(v) = \mu_t(p_s^0 v) \to \mu_t(v),\ s \downarrow 0$.
(v) Since $\langle\mu_t, v\rangle$ is increasing as $t \downarrow 0$ (independent of t when v is p_t^0-invariant), the assertions follow from

$$\langle m_0 - m_0 p_t^0, v\rangle = \int_0^t \langle\mu_s, v\rangle ds.$$

(vi) Since $S(t)$ is the right continuous inverse of an increasing continuous process $L(t)$, $P_a(S(t) > 0) = 1$ and consequently we have

$$L(m_0, \varphi) = \lim_{\alpha\to\infty} \alpha(u_\alpha, \varphi) = \infty$$

by letting $\alpha \to \infty$ in (2.21). □

We see by the above lemma that $\mu_t(\varphi)$ is decreasing and right continuous in $t > 0$ and so we can define a measure Θ on $(0, \infty)$ by

$$\Theta((s, t]) = \mu_s(\varphi) - \mu_t(\varphi), \quad 0 < s < t. \tag{2.24}$$

It then holds that

$$\Theta((s,t]) = \mu_s(\varphi - p^0_{t-s}\varphi) = \langle \mu_s, P_\cdot(\sigma \le t-s)\rangle,$$

and we get by letting $t \to \infty$,

$$\Theta((s,\infty)) = \mu_s(\varphi). \tag{2.25}$$

We note that

$$\Theta([\delta,\infty)) < \infty$$

for each $\delta > 0$ by virtue of Lemma 2.2 (iii).

Lemma 2.3. *It holds that*

$$\alpha(u_\alpha, \varphi) = \int_0^\infty \left(1 - e^{-\alpha u}\right)\Theta(du).$$

Proof. we have from Lemma 2.2 (ii) and (2.25)

$$\begin{aligned}
\alpha(u_\alpha,\varphi) &= \alpha\hat{\mu}_\alpha(\varphi) = \alpha\int_0^\infty e^{-\alpha t}\Theta((t,\infty))dt \\
&= \int_0^\infty \int_0^s \alpha e^{-\alpha t} dt \Theta(ds) = \int_0^\infty (1-e^{-\alpha s})\Theta(ds).
\end{aligned}$$

□

On account of the formula (2.21), Lemma 2.3 and by noting that $\lim_{\alpha\downarrow 0}\alpha(u_\alpha,\varphi) = 0$, we can get the next theorem from [2, Theorem 3.21].

Theorem 2.2. *Define a measure Θ on $(0,\infty)$ by (2.24). On a certain probablity space $(\Omega,\mathcal{B},P)$, construct a subordinator $\{Y_t\}_{t\ge 0}$ with Lévy measure Θ and zero drift and a random variable Z, independent of $\{Y_t\}$, with*

$$P(Z \ge t) = e^{-L(m_0,\psi)t}, \qquad t \ge 0.$$

If we let

$$S^*(t) = \begin{cases} Y(t) & t < Z, \\ \infty & t \ge Z, \end{cases}$$

then the process $(\{S^*(t)\}_{t\ge 0}, P)$ is equivalent in law to $(\{S(t)\}_{t\ge 0}, P_a)$.

3 Strongly local Dirichlet form with a recurrent point

Let S and m be as in §2. In this section, we consider a special case of the Dirichlet form of §2 for which the point a is recurrent.

3.1 Description of associated Poisson point process and entrance law

Let $(\mathcal{E},\mathcal{F})$ be a strongly local regular Dirichlet form on $L^2(S;m)$ and $X = (X_t, P_x)$ be an associated diffusion on S. In place of the assumption **B**.**1** of §2, let us assume that
B.**2** $\varphi(x) > 0 \qquad m-\text{a.e. } x \in S_0$
B.**3** $1 \in \mathcal{F}_e$ and $\mathcal{E}(1,1) = 0$.

In the next subsection, we shall construct a typical example of a Dirichlet form $(\mathcal{E},\mathcal{F})$ satisfying these conditions by a method of the one point compactification.

The assumption **B**.**2** implies that $u_1 > 0$, m-a.e. and $\text{Cap}(\{a\}) = \mathcal{E}_1(u_1,u_1) \geq (u_1,u_1) > 0$, namely, the assumption **B**.**1** of §1 (cf. [9, Lemma 4.2.1]). Further, the Dirichlet form $(\mathcal{E},\mathcal{F})$ becomes irreducible because, from (2.15), we have for any Borel sets $B_1, B_2 \subset S$ of positive m-measures

$$(I_E, G_\alpha I_F) \geq (u_\alpha, I_E)(u_\alpha, I_F)/\alpha(u_\alpha,\varphi) > 0.$$

Since $(\mathcal{E},\mathcal{F})$ is recurrent by **B**.**3**, we have actually the property

$$\varphi(x) = 1, \qquad \text{q.e. } x \in S, \tag{3.1}$$

stronger than the assumption **B**.**2** in view of [9, Th.4.6.6].

Thus the point a is not only regular for itself, instantaneous, but also recurrent. (2.15) is now reduced to

$$G_\alpha f(x) = G_\alpha^0 f(x) + \frac{(u_\alpha, f)}{\alpha(u_\alpha,1)} u_\alpha(x),\ x \in S, \quad G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha,1)}. \tag{3.2}$$

The positive continuous additive functional $L(t)$ of X associated with the unit mass δ_a has the property that $L(\infty) = \infty$ and its right continuous inverse $S(t)$ is a subordinator satisfying

$$E_a\left(\int_0^\infty e^{-\alpha S(s)} ds\right) = \frac{1}{\alpha(u_\alpha,1)} \tag{3.3}$$

on account of (2.16) and (2.20).

Therefore we can follow directly the argument of [15, §6 case 2(b)] to conclude that

$$D_{\mathbf{p}} = \{s : S(s) - S(s-) > 0\}, \tag{3.4}$$

$$\mathbf{p}_s(t) = X_{S(s-)+t},\ s \in D_{\mathbf{p}},\ 0 \leq t < S(s) - S(s-), \tag{3.5}$$

defines, under the law P_a, a W_a-valued Poisson point process $\mathbf{p}$, where W_a is the space of continous excursions in S_0 from a to a:

$$W_a = \{w : [0,\zeta(\omega)) \to S_0,\ \text{continuous},\ 0 < \zeta(\omega) < \infty, w(0) = a, w(\zeta-) = a\}. \tag{3.6}$$

Let $\mathbf{n}$ be the characteristic measure of the Poisson point process $\mathbf{p}$. Then $\mathbf{n}$ is a σ-finite measure on the space W_a and $\{w(t),\mathbf{n}\}$ is Markovian with respect to the transition function p_t^0 of X^0. The *entrance law* $\{\nu_t\}$ *associated with the characteristic measure* $\mathbf{n}$ is defined by

$$\nu_t(B) = \mathbf{n}\{w : \zeta(w) > t,\ w(t) \in B\}, \quad B \in \mathcal{B}(S),\ t > 0. \tag{3.7}$$

Recall that we have already considered an X^0-entrance law $\{\mu_t\}$ specified by (2.22) which is now reduced to

$$m = \int_0^\infty \mu_t\ dt. \tag{3.8}$$

The description (2.23) of $\{\mu_t\}$ now reads

$$\int_0^t \mu_s(f) ds = \int_{S_0} P_x^0(\zeta^0 \leq t) f(x) m(dx),\ t > 0,\ f \in \mathcal{B}(S_0). \tag{3.9}$$

Theorem 3.1. $\nu_t = \mu_t, \qquad t > 0.$

Proof. By virtue of Lemma 2.2, it suffices to show that

$$\hat{\nu}_\alpha(f) = (u_\alpha, f), \qquad f \in \mathcal{B}_b(S_0). \tag{3.10}$$

We make use of the next general formula

$$E_a\left(\sum_{s\le t} a(s, \mathbf{p}_s, \omega)\right) = E_a\left(\int_{W_a\times(0,t]} a(s,w,\omega)\mathbf{n}(dw)ds\right) \tag{3.11}$$

holding for any non-negative predictable function $a(s,w,\omega)$ on $[0,\infty)\times W_a\times\Omega$, Ω being a filtered sample space on which the diffusion process X is defined (cf. [14, p62].)

Since $m(\{a\})$ is assumed to be zero, $\int_0^\infty I_a(X_t)dt = 0$, P_a-almost surely. By (3.4) and (3.5), we have for $f \in B_b(S)$,

$$\begin{aligned} G_\alpha f(a) &= E_a\left(\int_0^\infty e^{-\alpha t} f(X_t)dt\right) = E_a\left(\sum_{s>0}\int_{S(s-)}^{S(s)} e^{-\alpha t} f(X_t)dt\right) \\ &= E_a\left(\sum_{s>0} e^{-\alpha S(s-)}\int_0^{\zeta(\mathbf{p}_s)} e^{-\alpha t} f(\mathbf{p}_s(t))dt\right). \end{aligned}$$

We let

$$\Gamma(w) = \int_0^{\zeta(w)} e^{-\alpha t} f(w(t))dt.$$

$a(s,w,\omega) = \Gamma(w)\cdot e^{-\alpha S(s-,\omega)}$ is then predictable and we get by (3.11)

$$\begin{aligned} G_\alpha f(a) &= E_a\left(\sum_{s>0} e^{-\alpha S(s-)}\Gamma(\mathbf{p}_s)\right) \\ &= \int_{W_a}\Gamma(w)\mathbf{n}(dw)\cdot\int_0^\infty E_a\left(e^{-\alpha S(s)}\right)ds. \end{aligned}$$

Since

$$\int_{W_a}\Gamma(w)\mathbf{n}(dw) = \hat{\nu}_\alpha(f),$$

(3.2) and (3.3) lead us to the desired identity (3.10). □

By Theorem 3.1 and [15, Th. 6.3], the finite dimensional distribution of $\{W_a, \mathbf{n}\}$ can be described as follows:

$$\int_{W_a} f_1(w(t_1))f_2(w(t_2))\cdots f_n(w(t_n))\mathbf{n}(dw) = \mu_{t_1} f_1 p^0_{t_2-t_1} f_2\cdots p^0_{t_{n-1}-t_{n-2}} f_{n-1} p^0_{t_n-t_{n-1}} f_n, \tag{3.12}$$

for any $0 < t_1 < t_2 < \cdots < t_{n-1}, t_n,\ f_1, f_2, \cdots, f_n \in B_b(S_0)$. Here we use the convention that $w \in W$ satisfies $w(t) = \Delta, \forall t \ge \zeta(w)$, and any function f on S_0 is extended to $S_0\cup\Delta$ by setting $f(\Delta) = 0$.

In §4, we shall start with an m-symmetric diffusion X^0 on S_0 and an expression like the above with μ_t being specified by (2.22). See §4 for the abbrevaited notation appearing on the right hand side of (3.12).

Actually Theorem 3.1 can be extended to a general case where condition **B.3** of the recurrence is not assumed as we shall see in Remark 4.2 at the end of §4.

We note that the excursion law around a regular point of a general Markov process can be also formulated in terms of Maisonneuve's exit system[5]. Some property of the integral in t of the associated entrance law was investigated by R.K. Getoor [10].

3.2 Construction of form by one-point compactification

In this subsection, we start with a Dirichlet form with underlying space S_0 and extend it by the one-point compactification to a Dirichlet form with underlying space $S = S_0 \cup a$ satisfying **B.2** and **B.3** (and consequently **B.1**).

Let S_0 be a locally compact separable metric space and m be a bounded positive measure on S_0 with $\mathrm{Supp}[m] = S_0$. We consider a regular strongly local Dirichlet form $(\mathcal{E}, \mathcal{F}_0)$ on $L^2(S_0; m)$ satisfying the *Poincaré inequailty*:

$$(u, u) \le A \cdot \mathcal{E}(u, u) \qquad u \in \mathcal{F}_0 \qquad \exists A > 0. \tag{3.13}$$

Denote by $S = S_0 \cup a$ the one-point compactification of S_0 and by $L^2(S; m)(= L^2(S_0; m))$ the space of square integrable functions on S with respect to $I_{S_0} \cdot m$. Let us introduce a space $(\mathcal{E}, \mathcal{F})$ by

$$\mathcal{F} = \mathcal{F}_0 + \text{ constant functions on } S, \tag{3.14}$$
$$\mathcal{E}(w_1, w_2) = \mathcal{E}(f_1, f_2),\ w_1 = f_1 + c_1,\ w_2 = f_2 + c_2,\ f_i \in \mathcal{F}_0,\ c_i \text{ constant}. \tag{3.15}$$

Theorem 3.2. (i) $(\mathcal{E}, \mathcal{F})$ *is a regular strongly local Dirichlet form on* $L^2(S; m)$ *possessing as its core the space*

$$\mathcal{C} = \mathcal{C}_0 + \text{ constant functions on } S_0,$$

where $\mathcal{C}_0 = \mathcal{F}_0 \cap C_0(S_0)$.
(ii) $(\mathcal{E}, \mathcal{F})$ *and the associated diffusion on* S *satisfy* **B.2**, **B.3**.

Proof. (i) Suppose $f \in \mathcal{F}_0$ is a constant. By the regularity of $(\mathcal{E}, \mathcal{F}_0)$, there exist $f_n \in \mathcal{F}_0 \cap C_0(S_0)$ which are $\mathcal{E}_1$-convergent to f. We have then $\mathcal{E}(f, f) = \lim_{n\to\infty} \mathcal{E}(f, f_n) = 0$ on account of the strong locality of $(\mathcal{E}, \mathcal{F}_0)$ and Remark 2.1 stated in the beginning of §2.1. (3.13) then implies $f = 0$ and the definition (3.14) and (3.15) makes sense.

If $w_n = f_n + c_n \in \mathcal{F}$ is an $\mathcal{E}_1$-Cauchy sequence、then f_n is $\mathcal{E}_1$-convergent to some $f \in \mathcal{F}_0$ by (3.13) and hence w_n is $\mathcal{E}_1$-convergent to $f + c$ for some constant c.

Clearly $\mathcal{C}$ is dense both in $\mathcal{F}$ and $C(S)$, namely, $(\mathcal{E}, \mathcal{F})$ is regular.

Suppose, for $w_i = f_i + c_i \in \mathcal{C}$, that w_1 is constant on a neighbourhood of $\mathrm{Supp}(w_2)$. When $c_2 = 0$, $\mathcal{E}(w_1, w_2) = 0$ by the strong locality of $(\mathcal{E}, \mathcal{F}_0)$. When $c_2 \ne 0$, the set $U = S \setminus \mathrm{Supp}(w_2)$ is either empty or a non-empty relatively compact open subset of S_0. In the former case, $f_1 = 0$ and $\mathcal{E}(w_1, w_2) = 0$. In the latter case, $f_2 = -c_2$ on U, while $\mathrm{Supp}(f_1) \subset U$ and $\mathcal{E}(w_1, w_2) = \mathcal{E}(f_1, f_2) = 0$ again. Hence $(\mathcal{E}, \mathcal{F})$ is strongly local on account of [9, Th.3.1.2].

The Markov property

$$w \in \mathcal{F} \Rightarrow v = (0 \vee w) \wedge 1 \in \mathcal{F}, \mathcal{E}(v, v) \le \mathcal{E}(w, w)$$

is evident, because, for $w = f + c,\ w \in \mathcal{F}_0,\ c$ constant, we have $v = [(-c) \vee f] \wedge (1 - c) + c$.

(ii) **B.2** follows from the Poincaré inequality (3.13). Denote by X and $X^0 = (X_t^0,\ P_x^0,\ \zeta^0)$ the diffusions associated with $(\mathcal{E}, \mathcal{F})$ and $(\mathcal{E}, \mathcal{F}_0)$ respectively. Then X^0 is the part of X on S_0 and hence

$$\varphi(x) = P_x^0(\zeta^0 < \infty), \qquad x \in S_0,$$

Denote by G^0 the 0-order resolvent operator of X^0. Since $m(S_0) < \infty$, (3.13) implies that $G^0 1 \in \mathcal{F}_0$ and

$$E_x^0(\zeta^0) = G^0 1(x) < \infty \qquad \text{q.e.}$$

proving (3.1). It is obvious from (3.14),(3.15) that $1 \in \mathcal{F}$ and $\mathcal{E}(1,1) = 0$. □

$(\mathcal{E}, \mathcal{F}_0)$ is not necessarily irreducible on S_0, but $(\mathcal{E}, \mathcal{F})$ defined by (3.14),(3.15) is irreducible recurrent on S in view of the observation made in the preceding subsection. See Example 6.2.

4 Construction of a symmetric extension via excursion valued Poisson point processes

In this section, we start with an m-symmetric diffusion X^0 on S_0 and construct first an excursion law with which Poisson point processes of two different kinds of excusions around the point a are associated. We then construct an m-symmetric diffusion $\tilde{X}$ on $S = S_0 \cup a$ by piecing together those excursions. The resolvent of the resulting diffusion $\tilde{X}$ turns out to be identical with (2.15).

4.1 An excursion law and its basic properties

Let S be a locally compact separable metric space and a be a non-isolated point of S. We put $S_0 = S \setminus \{a\}$. The one point compactification of S is denoted by S_Δ. When S is compact already, Δ is added as an isolated point. Let m be a positive Radon measure on S_0 with $\text{Supp}[m] = S_0$. m is extended to S by setting $m(\{a\}) = 0$.

We assume that we are given an m-symmetric diffusion $X^0 = (X_t^0, P_x^0)$ on S_0 with life time ζ^0 satisfying the following:

A.1 $\quad P_x^0(\zeta^0 < \infty,\ X_{\zeta^0-}^0 \in \{a\} \cup \{\Delta\}) = P_x^0(\zeta^0 < \infty), \quad \forall x \in S_0.$

We define the functions $\varphi, u_\alpha, \psi^{(1)}, \psi^{(2)}, \psi$ by (2.5) and (2.6), namely, for $x \in S_0$,

$$\varphi(x) = P_x^0(\zeta^0 < \infty,\ X_{\zeta^0-}^0 = a), \quad u_\alpha(x) = E_x^0(e^{-\alpha\zeta^0}; X_{\zeta^0-} = a),$$

$$\psi = 1 - \varphi = \psi^{(1)} + \psi^{(2)}, \quad \psi^{(1)}(x) = P_x^0(\zeta^0 < \infty,\ X_{\zeta^0-} = \Delta),\ \psi^{(2)}(x) = P_x^0(\zeta^0 = \infty).$$

Let us assume that

A.2 $\quad \varphi(x) > 0, \qquad \forall x \in S_0,$

and

A.3 $\quad u_\alpha \in L^1(S_0; m), \qquad \forall \alpha > 0.$

Denote by $p_t^0,\ G_\alpha^0$ the transition function and the resolvent of X^0 respectively. Our last assumption concerns the regularity:

A.4 $\quad u_\alpha \in C_b(S_0), \qquad G^0_\alpha(C_b(S_0)) \subset C_b(S_0), \qquad \alpha > 0,$

where $C_b(S_0)$ is the space of all bounded continuous functions on S_0.

The measure m could be infinite on a compact neighbourhood of a in S, but it is finite on each level set of u_α due to the condition **A.3**. We also note here the next relation which will be utilized in the sequel:

$$u_\alpha(x) = \varphi(x) - \alpha G^0_\alpha \varphi(x) \leq 1 - \alpha G^0_\alpha 1(x),\ x \in S_0.$$

Define m_0 by

$$m_0 = \varphi \cdot m,$$

which is an X^0-excessive measure with $m_0 p^0_t = p^0_t \varphi \cdot m$. In view of Lemma 2.2, there exists a unique X^0-entrance law $\{\mu_t\}$ related to the measure m_0 by (2.22), namely,

$$m_0 = \int_0^\infty \mu_t \ dt.$$

and it satisfies that

$$\hat{\mu}_\alpha(f) = (u_\alpha, f),\ f \in \mathcal{B}^+(S_0). \tag{4.1}$$

On account of the assumption **(A.3)**, we then have that

$$\mu_t(S_0) < \infty, \quad t > 0, \qquad \int_0^1 \mu_t(S_0) dt < \infty. \tag{4.2}$$

We now introduce the spaces $W',\ W$ of excursions by

$$W' = \{w : \exists \zeta(w) \in (0, \infty],\ w \text{ is a continuous function from } (0, \zeta(w)) \text{ to } S_0\},$$

$$W = \{w \in W' : \text{if } \zeta(w) < \infty, \text{ then } \exists w(\zeta(w)-) \in \{a\} \cup \{\Delta\}\}. \tag{4.3}$$

$\zeta(w)$ will be called the *terminal time* of the excursion w.

We are concerned with a measure $\mathbf{n}$ on the space W specified in terms of the entrance law $\{\mu_t\}$ and the transition function p^0_t by

$$\int_W f_1(w(t_1)) f_2(w(t_2)) \cdots f_n(w(t_n)) \mathbf{n}(dw) = \mu_{t_1} f_1 p^0_{t_2 - t_1} f_2 \cdots p^0_{t_{n-1} - t_{n-2}} f_{n-1} p^0_{t_n - t_{n-1}} f_n, \tag{4.4}$$

for any $0 < t_1 < t_2 < \cdots < t_n,\ f_1, f_2, \cdots, f_n \in B_b(S_0)$. Here, we use the convention that $w \in W$ satisfies $w(t) = \Delta, \forall t \geq \zeta(w)$, and any function f on S_0 is extended to $S_0 \cup \Delta$ by setting $f(\Delta) = 0$. Further, on the right hand side of (4.4), we employ an abbreviated notation for the repeated operations

$$\mu_{t_1}[f_1 p^0_{t_2 - t_1}\{f_2 \cdots p^0_{t_{n-1} - t_{n-2}}(f_{n-1} p^0_{t_n - t_{n-1}} f_n)\}].$$

Proposition 4.1. *There exists a unique measure* $\mathbf{n}$ *on the space* W *satisfiying* (4.4).

Proof. Let $\mathbf{n}$ be the Kuznetsov measure on W' uniquely associated with the transition semigroup $\{p_t^0\}$ and the entrance rule $\{\eta_u\}$ defined by

$$\eta_u = 0 \quad \text{for } u \leq 0, \quad \eta_u = \mu_u \quad \text{for } u > 0$$

as is constructed in [5, Chap XIX, 9] for a right semigroup. Because of the present choice of the entrance rule, it holds that $\alpha = 0$ where α is the birth time which is random in general(cf. [11, p54].)

On account of the assumption **A.1** for the diffusion X^0 on S_0, the same method of the construction of the Kuznetsov measure as in [5, Chap.XIX, 9] works in proving that $\mathbf{n}$ is supported by the space W and satisfies (4.4). □

We call $\mathbf{n}$ the *excursion law* associated with the entrance law $\{\mu_t\}$. We split the space W of excursions into two parts:

$$W^+ = \{w \in W : \zeta(w) < \infty,\ w(\zeta-) = a\}, \qquad W^- = W \setminus W^+. \tag{4.5}$$

Note that $W^- = W_1^- \cup W_2^-$ with

$$W_1^- = \{w \in W : \zeta(w) < \infty,\ w(\zeta-) = \Delta\},\ W_2^- = \{w \in W : \zeta(w) = \infty\}.$$

For $w \in W^+$, we define $\hat{w} \in W$ by

$$\hat{w}(t) = w(\zeta - t), \qquad 0 < t < \zeta. \tag{4.6}$$

The next lemma says that the restriction of the excursion law to W^+ is invariant under time reversion. This is a present variant of the time reversal arguments that have been formulated in general contexts ([23], [12], [6], [7]).

Lemma 4.1. *For any $t_k > 0$ and $f_k \in \mathcal{B}_b(S_0)$, $(1 \leq k \leq n)$,*

$$\mathbf{n}\left\{\prod_{k=1}^n f_k(w(t_1 + \cdots + t_k)); W^+\right\} = \mu_{t_1} f_1 p_{t_2}^0 f_2 \cdots p_{t_{n-1}}^0 f_{n-1} p_{t_n}^0 f_n \varphi, \tag{4.7}$$

$$\mathbf{n}\left\{\prod_{k=1}^n f_k(w(t_1 + \cdots + t_k)); W^+\right\} = \mathbf{n}\left\{\prod_{k=1}^n f_k(\hat{w}(t_1 + \cdots + t_k)); W^+\right\}. \tag{4.8}$$

Proof. (4.7) readily follows from (4.4) and the Markov property of $\mathbf{n}$. As for (4.8) we observe that, for $\alpha_1, \cdots, \alpha_n > 0$,

$$\int_0^\infty \cdots \int_0^\infty e^{-\alpha_1 t_1 - \cdots - \alpha_n t_n} \mathbf{n}\left\{\prod_{k=1}^n f_k(w(t_1 + \cdots + t_k)); W^+\right\} dt_1 \cdots dt_n \tag{4.9}$$

equals

$$\mathbf{n}\{F(w); \zeta < \infty,\ w(\zeta-) = a\}$$

with

$$F(w) = \int \cdots \int_{0 < t_1 < \cdots < t_n < \zeta} \prod_{k=1}^n \left\{e^{-\alpha_k(t_k - t_{k-1})} f_k(w(t_k))\right\} dt_1 \cdots dt_n,\ (t_0 = 0).$$

Hence, for (4.8), it suffices to prove

$$\mathbf{n}\{F(w);\zeta<\infty,\ w(\zeta-)=a\}=\mathbf{n}\{F(\hat{w});\zeta<\infty,\ w(\zeta-)=a\}. \tag{4.10}$$

Performing the change of variables

$$\zeta-t_k=s_k,\quad 1\le k\le n,$$

in the expression of $F(\hat{w})$ and by noting that

$$t_k=\zeta-s_k,\quad t_k-t_{k-1}=s_{k-1}-s_k,\quad 1\le k\le n,\quad s_0=\zeta,$$

$$0<t_1<\cdots<t_n<\zeta \Longleftrightarrow 0<s_n<\cdots<s_1<\zeta,$$

we obtain

$$\begin{aligned} F(\hat{w}) &= \int\cdots\int_{0<s_n<\cdots<s_1<\zeta}\prod_{k=1}^{n}\left\{e^{-\alpha_k(s_{k-1}-s_k)}f_k(w(s_k))\right\}ds_1\cdots ds_n \\ &= \int\cdots\int_{0<s_n<\cdots<s_1<\infty}\Gamma_{s_1\cdots s_n}(w)ds_1\cdots ds_n \end{aligned}$$

with

$$\Gamma_{s_1\cdots s_n}(w)=\prod_{k=2}^{n}\left\{e^{-\alpha_k(s_{k-1}-s_k)}f_k(w(s_k))\right\}\cdot e^{-\alpha_1(\zeta-s_1)}f_1(w(s_1))I_{(0,\zeta)}(s_1).$$

On the other hand, we get from (4.4) and the Markov property of $\mathbf{n}$ that

$$\begin{aligned} &\mathbf{n}\left\{\Gamma_{s_1s_2\cdots s_n}(w);\zeta<\infty,\ w(\zeta-)=a\right\} \\ &=\mathbf{n}\Big\{f_n(w(s_n))e^{-\alpha_n(s_{n-1}-s_n)}\cdots \\ &f_2((w(s_2))e^{-\alpha_3(s_1-s_2)}f_1(w(s_1)u_{\alpha_1}(w(s_1));s_1<\zeta\Big\} \\ &=e^{-\alpha_n(s_{n-1}-s_n)-\alpha_{n-1}(s_{n-2}-s_{n-1})-\cdots-\alpha_2(s_1-s_2)}\cdot \\ &\mu_{s_n}f_np^0_{s_{n-1}-s_n}f_{n-1}p^0_{s_{n-2}-s_{n-1}}f_{n-1}\cdots p^0_{s_2-s_3}f_2p^0_{s_1-s_2}f_1u_{\alpha_1}. \end{aligned}$$

Therefore,

$$\mathbf{n}\left\{F(\hat{w});\zeta<\infty,w(\zeta-)=a\right\}=\int_0^\infty ds_n\mu_{s_n}f_nG^0_{\alpha_n}f_{n-1}G^0_{\alpha_{n-1}}\cdots f_3G^0_{\alpha_3}f_2G^0_{\alpha_2}f_1u_{\alpha_1}.$$

In view of (2.7), the symmetry of G^0_α, (4.7) and (4.9), we arrive at

$$\begin{aligned} &\mathbf{n}\left\{F(\hat{w});\zeta<\infty,w(\zeta-)=a\right\}=\langle m_0,f_nG^0_{\alpha_n}f_{n-1}G^0_{\alpha_{n-1}}\cdots f_3G^0_{\alpha_3}f_2G_{\alpha_2}f_1u_{\alpha_1}\rangle \\ =\ &(f_n\varphi,G^0_{\alpha_n}f_{n-1}G^0_{\alpha_{n-1}}\cdots f_3G^0_{\alpha_3}f_2G_{\alpha_2}f_1u_{\alpha_1})=(f_1G^0_{\alpha_2}f_2G^0_{\alpha_3}f_3\cdots G_{\alpha_n}f_n\varphi,u_{\alpha_1}) \\ =\ &\int_0^\infty e^{-\alpha_1t_1}\mu_{t_1}f_1G^0_{\alpha_2}f_2G^0_{\alpha_3}f_3\cdots G^0_{\alpha_n}f_n\varphi dt_1=\mathbf{n}\left\{F(w);\zeta<\infty,w(\zeta-)=a\right\} \end{aligned}$$

the desired identity (4.10). □

Next we put

$$W_a=\{w\in W:\lim_{t\downarrow 0}w(t)=a\}. \tag{4.11}$$

Lemma 4.2. $\mathbf{n}\{W \setminus W_a\} = 0.$

Proof. The preceding lemma implies that

$$\begin{aligned}\mathbf{n}\left\{W^+ \setminus W_a\right\} &= \mathbf{n}\left\{W^+ \cap (w(0+) = a)^c\right\} \\ &= \mathbf{n}\left\{W^+ \cap (\hat{w}(0+) = a)^c\right\} = \mathbf{n}\left\{W^+ \cap (w(\zeta-) = a)^c\right\} = 0.\end{aligned}$$

We then have for each $t > 0$

$$\mathbf{n}\{\varphi(w(t)); (\zeta > t) \cap (w(0+) = a)^c\} = \mathbf{n}\left\{(W^+ \setminus W_a) \cap (\zeta > t)\right\} = 0,$$

which combined with the assumption **A.2** leads us to

$$\mathbf{n}\{(W \setminus W_a) \cap (\zeta > t)\} = 0.$$

It then suffices to let $t \downarrow 0$. □

Lemma 4.3. *For any neighbourhood U of a in S, we let*

$$\tau_{U^c} = \inf\{t > 0 : w(t) \in U^c\}, \qquad w \in W.$$

It holds then that

$$\mathbf{n}\{\tau_{U^c} < \zeta\} < \infty.$$

Proof. We may assume that the closure $\overline{U}$ in S is compact. Let $f(x) = \varphi(x) - u_1(x),\ x \in S_0$. Then

$$f(x) = E_x^0\left\{1 - e^{-\zeta^0}; \zeta^0 < \infty, X_{\zeta^0-} = a\right\} > 0, \quad \forall x \in S_0.$$

Since $u_\alpha(x) - u_1(x) \uparrow f(x),\ \alpha \downarrow 0$, the assumption **A.3** implies that f is lower semicontinuous on S_0 and hence

$$c = \inf_{x \in \partial U} f(x)$$

is positive. We then have, for each $\delta > 0$ and $x \in \partial U$,

$$\begin{aligned}&P_x^0(\delta < \zeta^0 < \infty, X_{\zeta^0-} = a) \geq E_x^0\left\{1 - e^{-\zeta^0}; \delta < \zeta^0 < \infty, X_{\zeta^0-} = a\right\} \\ \geq\ & c - E_x^0\left\{1 - e^{-\zeta^0}; \zeta^0 \leq \delta, X_{\zeta^0-} = a\right\} \geq c - (1 - e^{-\delta}).\end{aligned}$$

Choose $\delta > 0$ so small that

$$r = c - (1 - e^{-\delta})$$

is positive. For such δ,

$$P_x^0(\delta < \zeta^0 < \infty, X_{\zeta^0-} = a) \geq r, \qquad \forall x \in \partial U. \tag{4.12}$$

We shall use the notation τ_{U^c} not only for $w \in W$ but also for the sample path of the Markov process X^0. Using the preceding lemma, (4.12) and (4.2), we are led to

$$\begin{aligned}&\mathbf{n}\{\tau_{U^c} < \zeta\} = \lim_{\epsilon \downarrow 0} \mathbf{n}\{\epsilon < \tau_{U^c} < \zeta\} = \lim_{\epsilon \downarrow 0} \int_U \mu_\epsilon(dx) P_x^0\left\{\tau_{U^c} < \zeta^0\right\} \\ \leq\ & \overline{\lim}_{\epsilon \downarrow 0} \int_U \mu_\epsilon(dx) E_x^0\left\{r^{-1} P^0_{X_{\tau_{U^c}}}(\delta < \zeta^0 < \infty, X_{\zeta^0-} = a); \tau_{U^c} < \zeta^0\right\} \\ \leq\ & r^{-1} \lim_{\epsilon \downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\delta < \zeta^0 < \infty, X_{\zeta^0-} = a) \leq r^{-1} \lim_{\epsilon \downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\delta < \zeta^0) \\ =\ & r^{-1} \lim_{\epsilon \downarrow 0} \mu_{\epsilon+\delta}(S_0) \leq r^{-1} \mu_\delta(S_0) < \infty.\end{aligned}$$

□

The next lemma states a relation of the excursion law $\mathbf{n}$ to energy functionals $L(m_0, v)$ introduced in Lemma 2.1.

Lemma 4.4.
(i) $\mathbf{n}(W^+) = L(m_0, \varphi),\ \mathbf{n}(W^-) = L(m_0, \psi),\ \mathbf{n}(W_i^-) = L(m_0, \psi^{(i)}),\ i = 1, 2.$
(ii) $\mathbf{n}(W_1^-) < \infty,\ \mathbf{n}(W_2^-) = \mu_t(\psi^{(2)}) = \alpha\hat{\mu}_\alpha(\psi^{(2)}) = \alpha(u_\alpha, \psi^{(2)}) < \infty,\ t > 0, \alpha > 0.$

Proof. (i) Since $\mathbf{n}(\zeta > t; W^+) = \langle \mu_t, \varphi \rangle$, the first identity follows from Lemma 2.2 (v) by letting $t \downarrow 0$. The proof of the other indentities is the same.
(ii) Take a neighbourhood U of a in S with compact $\overline{U}$. We have then by the preceding lemma

$$\mathbf{n}(W_1^-) = \mathbf{n}(\zeta < \infty, w(\zeta-) = \Delta) \le \mathbf{n}\left\{\tau_{U^c} < \zeta\right\} < \infty.$$

Since $\psi^{(2)}$ is p_t^0-invariant, the second assetion follows from (i), Lemma 2.1, Lemma 2.2 and assumption **A.3**. □

In particular, $\mathbf{n}(W^-) = \mathbf{n}(W_1^-) + \mathbf{n}(W_2^-)$ is finite. We shall see that $\mathbf{n}(W^+) = \infty$.

4.2 Poisson point processes on W_a and a new process X

By Lemma 4.2, the excursion law $\mathbf{n}$ is concentrated on the space W_a defined by (4.11). Accordingly, we consider the spaces

$$W_a^+ = \{w \in W^+ : \lim_{t\downarrow 0} w(t) = a\},\ W_a^- = \{w \in W^- : \lim_{t\downarrow 0} w(t) = a\},$$

so that $W_a = W_a^+ + W_a^-$. In the sequel however, we shall employ slightly modified but equivalent definitions of those spaces by extending each w from an S_0-valued excursion to S-valued continuous one as follows:

$$\begin{aligned} W_a = \ & \{w : \exists\zeta(w) \in (0, \infty],\ w \text{ is a continuous function from } [0, \zeta(w)) \text{ to } S, w(0) = a. \\ & \qquad w(t) \in S_0,\ t \in (0, \zeta(w)),\ w(\zeta(w)-) \in \{a\} \cup \{\Delta\} \text{ if } \zeta(w) < \infty\}, \end{aligned} \tag{4.13}$$

Any $w \in W_a$ for which $\zeta(w) < \infty, w(\zeta(w)-) = a$ will be regarded to be a continuous function from $[0, \zeta(w)]$ to S by setting $w(\zeta(w)) = a$. We further let

$$\begin{aligned} W_a^+ = \ & \{w : \exists\zeta(w) \in (0, \infty),\ w \text{ is a continuous function from } [0, \zeta(w)] \text{ to } S, \\ & \qquad w(t) \in S_0,\ t \in (0, \zeta(w)),\ w(0) = w(\zeta(w)) = a\}, \end{aligned} \tag{4.14}$$

$$W_a^- = W_a \setminus W_a^+. \tag{4.15}$$

The excursion law $\mathbf{n}$ will be considered to be a measure on W_a defined by (4.13) and we denote by $\mathbf{n}^+,\ \mathbf{n}^-$, the restrictions of $\mathbf{n}$ to $W_a^+,\ W_a^-$ defined by (4.14) and (4.15) respectively.

Let $\{\mathbf{p}_s, s > 0\}$ be a Poisson point process on W_a with characteristic measure $\mathbf{n}$ defined on an appropriate probability space (Ω, P). We then let

$$\mathbf{p}_s^+ = \begin{cases} \mathbf{p}_s & \text{if } \mathbf{p}_s \in W_a^+, \\ \partial & \text{otherwise,} \end{cases} \tag{4.16}$$

$$\mathbf{p}_s^- = \begin{cases} \mathbf{p}_s & \text{if } \mathbf{p}_s \in W_a^-, \\ \partial & \text{otherwise,} \end{cases} \tag{4.17}$$

where ∂ is an extra point disjoint of W_a. Then $\{\mathbf{p}_s^+, s > 0\}$, $\{\mathbf{p}_s^-, s > 0\}$ are mutually independent Poisson point processes on W_a^+, W_a^- with characteristic measures $\mathbf{n}^+$, $\mathbf{n}^-$ respectively. Furthermore

$$\mathbf{p}_s = \mathbf{p}_s^+ \ + \ \mathbf{p}_s^-. \tag{4.18}$$

By means of the terminal time $\zeta(\mathbf{p}_r^+)$ of the excursion $\mathbf{p}_r^+$, we let

$$J(s) = \sum_{r \le s} \zeta(\mathbf{p}_r^+), \quad s > 0. \tag{4.19}$$

We put $J(0) = 0$.

Lemma 4.5. (i) $J(s) < \infty$ a.s. *for* $s > 0$.
(ii) $\{J(s)\}_{s \ge 0}$ *is a subordinator with*

$$E\left\{e^{-\alpha J(s)}\right\} = \exp\left\{-\alpha(u_\alpha, \varphi)s\right\}. \tag{4.20}$$

Proof. (i) We write $J(s)$ as $J(s) = I \ + \ II$ with

$$I = \sum_{r \le s, \zeta(\mathbf{p}_r^+) \le 1} \zeta(\mathbf{p}_r^+), \quad II = \sum_{r \le s, \zeta(\mathbf{p}_r^+) > 1} \zeta(\mathbf{p}_r^+).$$

Since $\mathbf{n}^+(\zeta > 1) \le \mu_1(S_0) < \infty$ by (4.2), r in the sum II is finite a.s. and hence $II < \infty$ a.s. On the other hand,

$$\begin{aligned} E(I) &= s\mathbf{n}^+(\zeta; \zeta \le 1) \le s\mathbf{n}^+(\zeta \wedge 1) \\ &= s\mathbf{n}^+\left\{\int_0^1 I_{(0,\zeta)}(t)dt\right\} = s\int_0^1 \mathbf{n}^+(\zeta > t)dt \le s\int_0^1 \mu_t(S_0)dt, \end{aligned}$$

which is finite by (4.2). Hence $I < \infty$ a.s.
(ii) Clearly $\{J(s)\}_{s \ge 0}$ is increasing and of stationary independent increment. Since

$$e^{-\alpha J(s)} - 1 = \sum_{r \le s}\left\{e^{-\alpha J(r)} - e^{-\alpha J(r-)}\right\} = \sum_{r \le s} e^{-\alpha J(r-)}\left\{e^{-\alpha\zeta(\mathbf{p}_r^+)} - 1\right\},$$

we have

$$E\left\{e^{-\alpha J(s)}\right\} - 1 = -c\int_0^s E\left\{e^{-\alpha J(r)}\right\}dr,$$

with

$$\begin{aligned} c &= \mathbf{n}^+(1 - e^{-\alpha\zeta}) = \mathbf{n}(1 - e^{-\alpha\zeta}; \zeta < \infty, w(\zeta) = a) \\ &= \mathbf{n}\left\{\alpha\int_0^\zeta e^{-\alpha t}dt; \zeta < \infty, w(\zeta) = a\right\} \\ &= \alpha\int_0^\infty e^{-\alpha t}\mathbf{n}(t < \zeta < \infty, w(\zeta) = a)dt \\ &= \alpha\int_0^\infty e^{-\alpha t}\mu_t(\varphi)dt = \alpha\hat{\mu}_\alpha(\varphi) = \alpha(u_\alpha, \varphi) < \infty. \end{aligned}$$

□

In virtue of Lemma 4.3 and Lemma 4.5, we may assume that the next three properties hold for any $\omega \in \Omega$ by subtracting a P-negligible set from Ω if necessary:

$$J(s) < \infty \qquad \forall s > 0, \tag{4.21}$$

$$\lim_{s\to\infty} J(s) = \infty, \tag{4.22}$$

and, for any finite interval $I \subset (0, \infty)$ and any neighbourhood U of a in S,

$$\left\{s \in I : \tau_{U^c}(\mathbf{p}_s^+) < \zeta(\mathbf{p}_s^+)\right\} \text{ is a finite set.} \tag{4.23}$$

Let T be the time of occurrence of the first excursion of the point process $\{\mathbf{p}_s^-, s > 0\}$, namely,

$$T = \min\{s > 0 : \mathbf{p}_s^- \neq \partial\}. \tag{4.24}$$

Since $\mathbf{n}(W_a^-) = L(m_0, \psi) < \infty$ by Lemma 4.4, we can see that T and $\mathbf{p}_T^-$ are independent and

$$P(T > t) = e^{-L(m_0,\psi)t}, \qquad \text{the distribution of } \mathbf{p}_T^- = L(m_0, \psi)^{-1}\mathbf{n}^-. \tag{4.25}$$

We are now in a position to produce a new process $X = \{X_t\}_{t\geq 0}$ out of the point processes of excursions $\mathbf{p}^\pm$.
(i) For $0 \leq t < J(T-)$, we determine s by

$$J(s-) \leq t \leq J(s), \tag{4.26}$$

and let

$$X_t = \begin{cases} \mathbf{p}_s^+(t - J(s-)) & \text{if } J(s) - J(s-) > 0, \\ a & \text{if } J(s) - J(s-) = 0. \end{cases} \tag{4.27}$$

(ii) For $J(T-) \leq t < \zeta_\omega \equiv J(T-) + \zeta(\mathbf{p}_T^-)$, we let

$$X_t = \mathbf{p}_T^-(t - J(T-)). \tag{4.28}$$

In this way, the S-valued continuous path

$$X_t, \ 0 \leq t < \zeta_\omega,$$

is defined and

$$X_{\zeta_\omega -} = \Delta \quad \text{if } \zeta_\omega < \infty.$$

Continuity of the path is a consequaence of (4.23).

For this process $\{X_t, 0 \leq t < \zeta_\omega, P\}$, let us put

$$G_\alpha f(a) = E\left(\int_0^{\zeta_\omega} e^{-\alpha t} f(X_t)dt\right), \quad \alpha > 0, \ f \in \mathcal{B}(S). \tag{4.29}$$

Proposition 4.2. *It holds that*

$$G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi)}. \tag{4.30}$$

Proof. We use the notation

$$\hat{f}_\alpha(w) = \int_0^{\zeta(w)} e^{-\alpha t} f(w(t))dt, \quad w \in W_a.$$

We have then

$$\begin{aligned}\int_0^{\zeta_\omega} e^{-\alpha t} f(X_t)dt &= \sum_{s<T} \int_{J(s-)}^{J(s)} e^{-\alpha t} f(X_t)dt + \int_{J(T-)}^{J(T-)+\zeta(\mathbf{p}_T^-)} e^{-\alpha t} f(X_t)dt \\ &= \sum_{s<T} e^{-\alpha J(s-)} \hat{f}_\alpha(\mathbf{p}_s^+) + e^{-\alpha J(T-)} \hat{f}_\alpha(\mathbf{p}_T^-),\end{aligned}$$

and consequently

$$\begin{aligned}G_\alpha f(a) &= E\left(\sum_{s<T} e^{-\alpha J(s-)} \hat{f}_\alpha(\mathbf{p}_s^+) + e^{-\alpha J(T-)} \hat{f}_\alpha(\mathbf{p}_T^-)\right) \\ &= E\left(\int_0^T e^{-\alpha\hat{\mu}_\alpha(\varphi)s} ds\right) \mathbf{n}^+(\hat{f}_\alpha) + E\left(e^{-\alpha\hat{\mu}_\alpha(\varphi)T}\right) L(m_0, \psi)^{-1} \mathbf{n}^-(\hat{f}_\alpha) \\ &= \frac{\mathbf{n}^+(\hat{f}_\alpha)}{\alpha\hat{\mu}_\alpha(\varphi) + L(m_0, \psi)} + \frac{\mathbf{n}^-(\hat{f}_\alpha)}{\alpha\hat{\mu}_\alpha(\varphi) + L(m_0, \psi)} \\ &= \frac{\mathbf{n}(\hat{f}_\alpha)}{\alpha\hat{\mu}_\alpha(\varphi) + L(m_0, \psi)} = \frac{\hat{\mu}_\alpha(f)}{\alpha\hat{\mu}_\alpha(\varphi) + L(m_0, \psi)}.\end{aligned}$$

It then suffices to substitute (4.1) in the last expression. □

4.3 Continuity of resolvent along X

Lemma 4.6. *For $\alpha > 0$ and $f \in \mathcal{B}(S)$, define $G_\alpha f(a)$ by the right hand side of* (4.30) *and extend it to a function on S by setting*

$$G_\alpha f(x) = G_\alpha^0 f(x) + G_\alpha f(a) u_\alpha(x), \qquad x \in S_0. \tag{4.31}$$

Then $\{G_\alpha\}_{\alpha>0}$ is an m-symmetric (*sub*)*Markovian resolvent on S.*

Proof. By making use of the resolvent equation for G_α^0, the m-symmetry of G_α^0 and the equation

$$u_\alpha(x) - u_\beta(x) + (\alpha - \beta) G_\alpha^0 u_\beta(x) = 0, \quad \alpha, \beta > 0, \ x \in S_0,$$

we can easily check the resolvent equation

$$G_\alpha f(x) - G_\beta f(x) + (\alpha - \beta) G_\alpha G_\beta f(x) = 0, \quad x \in S.$$

The m-symmetry of G_α

$$\int_S G_\alpha f(x) g(x) m(dx) = \int_S f(x) G_\alpha g(x) m(dx)$$

holding for any non-negative Borel functions f, g is clear. Moreover we get by Lemma 2.1 that

$$\begin{aligned} \alpha G_\alpha 1(x) &= \alpha G_\alpha^0 1(x) + u_\alpha(x)\frac{\alpha(u_\alpha, \varphi+\psi)}{\alpha(u_\alpha,\varphi) + L(m_0,\psi)} \\ &\leq 1 - u_\alpha(x) + u_\alpha(x) = 1, \quad x \in S_0, \end{aligned}$$

and similarly, $\alpha G_\alpha 1(a) \leq 1$. □

Let $\{U_n\}$ be a decreasing sequence of open neighbourhoods of the point a in S such that $U_n \supset \overline{U}_{n+1}$ and $\cap_{n=1}^\infty U_n = \{a\}$. Let

$$A = A_{\alpha,\rho} = \{x \in S_0 : u_\alpha(x) < \rho\} \text{ for } \alpha > 0,\ 0 < \rho < 1.$$

We then set

$$\sigma_n = \inf\{t > 0 : X_t^0 \in U_n \cap S_0\},\ \sigma_a = \lim_{n\to\infty}\sigma_n,\ \tau_n = \inf\{t > 0 : X_t^0 \in U_n \cap A\},$$

with the convention that $\inf\emptyset = \infty$.

Lemma 4.7. *For any $\alpha > 0$, $\rho \in (0,1)$ and $x \in S_0$,*

$$\lim_{n\to\infty} P_x^0\{\tau_n < \sigma_a < \infty\} = 0. \tag{4.32}$$

Proof. Since

$$\{\sigma_a < \infty\} = \{\zeta^0 < \infty,\ X^0_{\zeta^0 -} = a\}$$

and $\sigma_a = \zeta^0$ on the set $\{\sigma_a < \infty\}$, we have for $x \in S_0$ and $m < n$

$$\begin{aligned} u_\alpha(x) &= E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n < \sigma_a\right\} + E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n \geq \sigma_a\right\} \\ &= E_x^0\left\{e^{-\alpha\tau_n}u_\alpha\left(X^0_{\tau_n}\right); \tau_n < \sigma_a\right\} + E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n \geq \sigma_a\right\} \\ &\leq \rho E_x^0\left\{e^{-\alpha\tau_n}; \tau_n < \sigma_a\right\} + E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n \geq \sigma_a\right\} \\ &\leq \rho E_x^0\left\{e^{-\alpha(\tau_n\wedge\sigma_a)}; \tau_m < \sigma_a\right\} + E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n \geq \sigma_a\right\}. \end{aligned}$$

By letting first $n \to \infty$ and then $m \to \infty$, we obtain

$$\begin{aligned} u_\alpha(x) &\leq \rho \lim_{m\to\infty} E_x^0\left\{e^{-\alpha\sigma_a}; \tau_m < \sigma_a\right\} + \lim_{n\to\infty} E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n \geq \sigma_a\right\} \\ &= E_x^0\left\{e^{-\alpha\sigma_a}\right\} - (1-\rho)\lim_{n\to\infty} E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n < \sigma_a\right\} \\ &= u_\alpha(x) - (1-\rho)\lim_{n\to\infty} E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n < \sigma_a\right\}, \end{aligned}$$

which implies

$$\lim_{n\to\infty} E_x^0\left\{e^{-\alpha\sigma_a}; \tau_n < \sigma_a\right\} = 0$$

and so (4.32) must hold. □

Lemma 4.8. *Let $\alpha > 0$.*
(i) *For any $x \in S_0$,*

$$\lim_{t\uparrow\sigma_a} u_\alpha(X_t^0) = 1 \quad P_x^0\text{-a.s. on } \{\sigma_a < \infty\}. \tag{4.33}$$

(ii) $\mathbf{n}(\Lambda) = 0$ *where*

$$\Lambda = \left\{w \in W_a^+ : \exists\alpha > 0,\ \lim_{t\uparrow\zeta} u_\alpha(w(t)) \neq 1\right\}.$$

Proof. If $\sigma_a < \infty$ and if $\underline{\lim}_{t\uparrow\sigma_a} u_\alpha(X_t^0) < \rho$, then for any small $\epsilon > 0$ there exists $t \in (\sigma_a - \epsilon, \sigma_a)$ such that $u_\alpha(X_t^0) < \rho$, and so $\tau_n < \sigma_a$ for all n. Therefore by the preceding lemma

$$P_x^0 \left\{\underline{\lim}_{t\uparrow\sigma_a} u_\alpha(X_t^0) < \rho,\ \sigma_a < \infty\right\} = 0.$$

Since u_α is decreasing in α and ρ can be taken arbitrarily close to 1, we obtain (4.33).

(ii) follows from (i) as

$$\begin{aligned}\mathbf{n}(\Lambda) &= \lim_{\epsilon\downarrow 0} \mathbf{n}(\Lambda \cap \{\epsilon < \zeta\}) \\ &= \lim_{\epsilon\downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\lim_{t\uparrow\sigma_a} u_\alpha(X_t^0) \neq 1) = 0.\end{aligned}$$

□

We extend u_α to a function on S by setting $u_\alpha(a) = 1$. By Lemma 4.8 (ii) combined with Lemma 4.1 and a similar reasoning as in the proof of Lemma 4.2, we may assume, subtracting a suitable $\mathbf{n}$-negligible set from W_a^+ (resp. W_a^-), that $u_1(w(t))$ is continuous in $t \in [0, \zeta]$ (resp. $t \in [0, \zeta)$.)

Lemma 4.9. *Let $0 < \rho < 1$ and set*

$$\tilde{W}_\rho = \left\{ w \in W_a^+ : \max_{0\le t\le\zeta} \{1 - u_1(w(t))\} > \rho \right\}.$$

Then $\mathbf{n}^+(\tilde{W}_\rho) < \infty$.

Proof. The proof is similar to that of Lemma 4.3. For any x such that $1 - u_1(x) = \rho$ and for $\delta = -\log(1 - \frac{\rho}{2}) > 0$, we have

$$\begin{aligned} & P_x^0(\sigma_a > \delta) \ge E_x^0 \left\{1 - e^{-\sigma_a}; \sigma_a > \delta\right\} \\ = \ & E_x^0 \left\{1 - e^{-\sigma_a}\right\} - E_x^0 \left\{1 - e^{-\sigma_a}; \sigma_a \le \delta\right\} \\ \ge \ & 1 - u_1(x) - (1 - e^{-\delta}) = \rho - (1 - e^{-\delta}) = \frac{\rho}{2}.\end{aligned}$$

Therefore if we set

$$A = \{x \in S_0 : 1 - u_1(x) \le \rho\}, \quad \tau = \inf\{t > 0 : w(t) \in S_0 \setminus A\},$$

then

$$\begin{aligned} & \mathbf{n}^+(\tilde{W}_\rho) = \mathbf{n}^+(\tau < \zeta) = \lim_{\epsilon\downarrow 0} \mathbf{n}^+(\epsilon < \tau < \zeta^0) = \lim_{\epsilon\downarrow 0} \int_A \mu_\epsilon(dx) P_x^0(\tau < \zeta^0) \\ \le \ & \overline{\lim}_{\epsilon\downarrow 0} \int_A \mu_\epsilon(dx) E_x^0 \left\{ \left(\frac{2}{\rho}\right) P^0_{X^0_\tau}(\sigma_a > \delta); \tau < \zeta^0 \right\} \\ \le \ & \frac{2}{\rho} \overline{\lim}_{\epsilon\downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\sigma_a > \delta) \\ \le \ & \frac{2}{\rho} \lim_{\epsilon\downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\zeta^0 > \delta) + \frac{2}{\rho} \lim_{\epsilon\downarrow 0} \int_{S_0} \mu_\epsilon(dx) P_x^0(\zeta^0 < \sigma_a = \infty) \\ = \ & \frac{2}{\rho} \lim_{\epsilon\downarrow 0} \mu_{\epsilon+\delta}(1) + \frac{2}{\rho} \lim_{\epsilon\downarrow 0} \mu_\epsilon(\psi^{(1)}),\end{aligned}$$

which is finite in view of (4.2) and Lemma 4.4. □

For $\alpha > 0,\ f \in \mathcal{B}(S)$, we defined the resolvent $G_\alpha f$ by

$$G_\alpha f(x) = G^0_\alpha f(x) + G_\alpha f(a) u_\alpha(x), \quad x \in S_0$$

with $G_\alpha f(a)$ of Proposition 4.2. We now extend $G^0_\alpha f(x)$ to S by setting

$$G^0_\alpha f(a) = 0.$$

In the last subsection, we have constructed a process $\{X_t\}_{t\in[0,\zeta_\omega)}$ out of the Poisson point processes $\mathbf{p}^+,\ \mathbf{p}^-$ on $W^+_a,\ W^-_a$ defined on a probability space (Ω, P).

Proposition 4.3. *Let $u = G_\alpha f$ with $f \in C_b(S)$. Then $u(X_t)$ is continuous in $t \in [0, \zeta_\omega)$, P-a.s.*

Proof. As was remarked immediately after the proof of Lemma 4.8, u_1 is continuous along any sample point functions of $\mathbf{p}^+ = \{\mathbf{p}^+_s, s > 0\}$ and $\mathbf{p}^- = \{\mathbf{p}^-_s, s > 0\}$. Moreover, by Lemma 4.9, we can subtract a suitable P-negligible set from Ω so that, in addition to the properties (4.21),(4.22) and (4.23), $\mathbf{p}^+$ satisfies the following property for every sample point $\omega \in \Omega$: for any finite interval $I \subset (0, \infty)$ and for any $\rho \in (0, 1)$,

$$\{s \in I : \max_{0\le t\le\zeta(\mathbf{p}^+_s)} (1 - u_1(\mathbf{p}^+_s(t))) > \rho\} \text{ is a finite set.} \tag{4.34}$$

Then it is not hard to see that not only X_t but also $u_1(X_t)$ are continuous in $t \in [0, \zeta_\omega)$. From the inequality $G^0_1 1(x) \le 1 - u_1(x),\ x \in S$, we see that

$$\lim_{t\to t_0} G^0_1 1(X_t) = 0 \quad \text{if } X_{t_0} = a.$$

Hence $G^0_1 f(X_t)$ has the same property as the above for $f \in C_b(S)$. Since $G^0_1 f(X_t)$ is clearly continuous on $\{t \in [0, \zeta_\omega) : X_t \ne a\}$ by the assumption **A.4**, it is continuous on $[0, \zeta_\omega)$. We have thus proved the continuity of $G_1 f(X_t)$. The continuity of $G_\alpha f(X_t)$ follows from the resolvent equation proved in Lemma 4.6. □

4.4 Markov property of X

Let us define $p_t f(x)$ for $t > 0, x \in S, f \in \mathcal{B}(S)$, as follows:

$$p_t f(a) = E\left(f(X_t); \zeta_\omega > t\right), \tag{4.35}$$

$$p_t f(x) = p^0_t f(x) + E^0_x \left\{p_{t-\sigma_a} f(a); \sigma_a \le t\right\},\ x \in S_0. \tag{4.36}$$

Evidently

$$\int_0^\infty e^{-\alpha t} p_t f dt = G_\alpha f, \qquad \alpha > 0. \tag{4.37}$$

Lemma 4.10. $p_{t+s} = p_t p_s, \qquad t,\ s > 0.$

Proof. Take any $f \in C_b(S)$. By (4.36) and the resolvent equation in Lemma 4.6, we have for any $x \in S$

$$\int_0^\infty e^{-\alpha t} \left\{\int_0^\infty e^{-\beta s} p_{t+s} f(x) ds\right\} dt = \int_0^\infty e^{-\alpha t} \left\{p_t(G_\beta f)(x)\right\} dt, \tag{4.38}$$

because the left hand side equals $\dfrac{1}{\alpha-\beta}(G_\beta f(x) - G_\alpha f(x)) = G_\alpha G_\beta f(x)$.

We first consider the case where $x = a$. Then the functions inside $\{\cdot\}$ of the both hand sides of (4.38) are continuous in $t > 0$ in virtue of the continuity of X and Proposition 4.3. Hence we have for any $t > 0$

$$\int_0^\infty e^{-\beta s} p_{t+s} f(a) ds = p_s(G_\beta f)(a) = \int_0^\infty e^{-\beta s} p_t(p_s f)(a) ds.$$

Since both $p_{t+s}f(a)$, $p_t(p_s f)(a)$ are right continuous in $s > 0$, we get

$$p_{t+s} f(a) = p_t(p_s f)(a), \qquad t > 0,\ s > 0. \tag{4.39}$$

We next consdier the case where $x \in S_0$. Using (4.37), we obtain

$$\begin{aligned} p_{t+s} f(x) &= p^0_{t+s} f(x) + E^0_x \{p_{t+s-\sigma_a} f(a); \sigma_a \le t+s\} \\ &= p^0_{t+s} f(x) + E^0_x \{p_{t-\sigma_a}(p_s f)(a); \sigma_a \le t\} \\ &+ E^0_x \{p_{t+s-\sigma_a} f(a) : t < \sigma_a \le t+s\}. \end{aligned}$$

On the other hand,

$$p_t(p_s f)(x) = p^0_t(p_s f)(x) + E^0_x \{p_{t-\sigma_a}(p_s f)(a); \sigma_a \le t\}.$$

Hence it suffices to prove that

$$p^0_{t+s} f(x) + E^0_x \{p_{t+s-\sigma_a} f(a); t < \sigma_a \le t+s\} = p^0_t(p_s f)(x). \tag{4.40}$$

Put

$$g(x) = E^0_x \{p_{s-\sigma_a} f(a); \sigma_a \le s\},$$

then, we are led from $p_s f(x) = p^0_s f(x) + g(x)$ to

$$p^0_t(p_s f)(x) = p^0_{t+s} f(x) + p^0_t g(x),$$

and consequently, (4.40) is reduced to

$$E^0_x \{p_{t+s-\sigma_a} f(a); t < \sigma_a \le t+s\} = E^0_x(g(X^0_t); \zeta^0 > t). \tag{4.41}$$

With the notation θ_t to denote the usual shift, the left hand side of (4.41) equals

$$\begin{aligned} & E^0_x \left\{p_{t+s-\sigma_a} f(a); \zeta^0 > t, \sigma_a > t, \sigma_a \circ \theta_t \le s\right\} \\ =\ & E^0_x \left\{p_{s-\sigma_a\circ\theta_t} f(a); \zeta^0 > t, \sigma_a \circ \theta_t \le s\right\} \\ =\ & E^0_x \left[E^0_{X^0_t} \{p_{s-\sigma_a} f(a); \sigma_a \le s\}; \zeta^0 > t\right], \end{aligned}$$

which coincides with the right hand side of (4.41) as was to be proved. □

Lemma 4.11. *Suppose $g \in \mathcal{B}(S)$ and $\lim_{\epsilon\downarrow 0} p_\epsilon g(x) = g(x)$, $x \in S$. Then, for any $f \in C_b(S)$, $t > 0$,*

$$\lim_{\epsilon\downarrow 0} p_\epsilon(f p_t g)(x) = f(x) p_t g(x), \quad x \in S. \tag{4.42}$$

Proof. Fix $x \in S$. Clearly, for any neighbourhood U of x,

$$\lim_{\epsilon \downarrow 0} p_\epsilon I_U(x) = 1,$$

and hence

$$p_\epsilon |f p_t g|(x) = p_\epsilon |f I_U p_t g|(x) + o(\epsilon).$$

For any $\delta > 0$, take a neighbourhood U of x such that

$$|f(y) - f(x)| < \delta, \qquad y \in U.$$

Then

$$\begin{aligned} & |p_\epsilon(f p_t g)(x) - f(x) p_\epsilon(p_t g)(x)| \\ \leq \; & p_\epsilon \left(|f - f(x)||p_t g| \right)(x) \\ \leq \; & p_\epsilon \left(|f - f(x)| I_U |p_t g| \right)(x) + o(\epsilon) \leq \delta ||g||_\infty + o(\epsilon). \end{aligned}$$

On the other hand, we have from the preceding lemma that

$$\lim_{\epsilon \downarrow 0} f(x) p_\epsilon(p_t g)(x) = \lim_{\epsilon \downarrow 0} f(x) p_t(p_\epsilon g)(x) = f(x) p_t g(x).$$

Consequently

$$\overline{\lim}_{\epsilon \downarrow 0} |p_\epsilon(f p_t g)(x) - f(x) p_t g(x)| \leq \delta ||g||_\infty,$$

which means (4.42) because $\delta > 0$ can be taken arbitrarily small. □

Proposition 4.4. (i) *For* $\alpha_1, \cdots, \alpha_n > 0$,

$$E \left\{ \int \cdots \int_{0 < t_1 < \cdots < t_n < \zeta_\omega} \prod_{k=1}^{n} \left(e^{-\alpha_k (t_k - t_{k-1})} f_k(X_{t_k}) \right) dt_1 \cdots dt_n \right\} = G_{\alpha_1} f_1 G_{\alpha_2} f_2 \cdots G_{\alpha_n} f_n(a), \tag{4.43}$$

where we set $t_0 = 0$ *by convention.*
(ii). $X = \{X_t, 0 \leq t < \zeta_\omega, P\}$ *is a Markov process on* S *with transition function* p_t *and initial distribution concentrated at* $\{a\}$.

Proof. We shall employ the following notations:

$$F(X; t; \alpha_1, f_1, \cdots, \alpha_n, f_n) = \int \cdots \int_{t < t_1 < \cdots < t_n < \zeta_\omega} \prod_{k=1}^{n} \left\{ e^{-\alpha_k (t_k - t_{k-1})} f_k(X_{t_k}) \right\} dt_1 \cdots dt_n,$$

and, for $w \in W_a$,

$$F(w; t; \alpha_1, f_1, \cdots, \alpha_n, f_n) = \int \cdots \int_{t < t_1 < \cdots < t_n < \zeta(w)} \prod_{k=1}^{n} \left\{ e^{-\alpha_k (t_k - t_{k-1})} f_k(w(t_k)) \right\} dt_1 \cdots dt_n.$$

(i). The left hand side of (4.43) will be denoted by $G(\alpha_1, f_1, \cdots, \alpha_n, f_n)$, namely,

$$E\left\{ F(X; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n) \right\} = G(\alpha_1, f_1, \cdots, \alpha_n, f_n). \tag{4.44}$$

For $0 < s < T$, we denote by $I(s)$ the expression

$$\int_{J(s-)<t_1<J(s)} e^{-\alpha_1 t_1} f_1(X_{t_1}) \left\{ \int \cdots \int_{t_1<t_2<\cdots<t_n<\zeta_\omega} \prod_{k=2}^{n} \left(e^{-\alpha_k (t_k - t_{k-1})} f_k(X_{t_k}) \right) dt_2 \cdots dt_n \right\} dt_1.$$

Then

$$F(X; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n) = \sum_{0<s<T} I(s) + F(X; J(T-); \alpha_1, f_1, \cdots, \alpha_n, f_n).$$

Further, if we put for $1 \leq m \leq n$

$$\begin{aligned} I_m(s) \quad &= \int \cdots \int_{J(s-)<t_1<\cdots<t_m<J(s)} \prod_{k=1}^{m} \left\{ e^{-\alpha_k (t_k - t_{k-1})} f_k(X_{t_k}) \right\} dt_1 \cdots dt_m \\ &\quad \cdot \int \cdots \int_{J(s)<t_{m+1}<\cdots<t_n<\zeta_\omega} \prod_{\ell=m+1}^{n} \left\{ e^{-\alpha_\ell (t_\ell - t_{\ell-1})} f_\ell(X_{t_\ell}) \right\} dt_{m+1} \cdots dt_n, \end{aligned}$$

then

$$I(s) = \sum_{m=1}^{n} I_m(s).$$

Moreover, each $I_m(s)$ can be written as

$$I_m(s) = F_m(s) G_m(s)$$

with

$$F_m(s) = \int \cdots \int_{J(s-)<t_1<\cdots<t_m<J(s)} \prod_{k=1}^{m} \left\{ e^{-\alpha_k (t_k - t_{k-1})} f_k(X_{t_k}) \right\} e^{-\alpha_{m+1}(J(s) - t_m)} dt_1 \cdots dt_m,$$

$$G_m(s) = \int \cdots \int_{J(s)<t_{m+1}<\cdots<t_n<\zeta_\omega} e^{-\alpha_{m+1}(t_{m+1} - J(s))} \prod_{\ell=m+2}^{n} \left\{ e^{-\alpha_\ell (t_\ell - t_{\ell-1})} f_\ell(X_{t_\ell}) \right\} dt_{m+1} \cdots dt_n.$$

Therefore

$$F(X; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n) = \sum_{0<s<T} \sum_{m=1}^{n} F_m(s) G_m(s) + F(X; J(T-); \alpha_1, f_1, \cdots, \alpha_n, f_n). \tag{4.45}$$

Next, let us put (with the convention that $\alpha_{n+1} = 0$)

$$\begin{aligned} &F(w; \alpha_1, f_1, \cdots, \alpha_m, f_m; \alpha_{m+1}) \\ &\quad = \int \cdots \int_{0<t_1<\cdots<t_m<\zeta(w)} \prod_{k=1}^{m} \left\{ e^{-\alpha_k (t_k - t_{k-1})} f_k(w(t_k)) \right\} e^{-\alpha_{m+1}(\zeta(w) - t_m)} dt_1 \cdots dt_m, \end{aligned} \tag{4.46}$$

so that

$$F_m(s) = e^{-\alpha_1 J(s-)} F(\mathbf{p}_s^+; \alpha_1, f_1, \cdots, \alpha_m, f_m; \alpha_{m+1}). \tag{4.47}$$

We furthrmore put $Y_t = X_{J(s)+t}$ so that

$$G_m(s) = \int\cdots\int_{0<t_{m+1}<\cdots<t_n<\zeta_\omega - J(s)} \prod_{\ell=m+1}^{n} \left\{ e^{-\alpha_\ell(t_\ell - t_{\ell-1})} f_\ell(X_{t_\ell}) \right\} dt_{m+1}\cdots dt_n, \tag{4.48}$$

where we set $t_m = 0$.

For $\mathbf{p} = \{\mathbf{p}_t, t > 0\}$, we may use the following notations:

$$\begin{aligned} &G(\mathbf{p}; \alpha_{m+1}, f_{m+1}, \cdots, \alpha_n, f_n) \\ &= \int\cdots\int_{0<t_{m+1}<\cdots<t_n<\zeta_\omega} \prod_{\ell=m+1}^{n} \left\{ e^{-\alpha_\ell(t_\ell - t_{\ell-1})} f_\ell(X_{t_\ell}) \right\} dt_{m+1}\cdots dt_n, \end{aligned} \tag{4.49}$$

(with the convention that $t_m = 0$), and

$$\theta_s \mathbf{p} = \{\mathbf{p}_{s+t}, t > 0\}. \tag{4.50}$$

$\theta_s\mathbf{p}$ then has the same distribution as $\mathbf{p}$ and independent of $\{\mathbf{p}_t, 0 < t < s\}$. Since Y_t is constructed from $\theta_s\mathbf{p}$ in the same way as X_t is from $\mathbf{p}$, (4.48) can be rewritten as

$$G_m(s) = G(\theta_s\mathbf{p}; \alpha_{m+1}, f_{m+1}, \cdots, \alpha_n, f_n), \tag{4.51}$$

which is identical in law to

$$G(\mathbf{p}; \alpha_{m+1}, f_{m+1}, \cdots, \alpha_n, f_n)$$

for each fixed $s > 0$. Further

$$F(X; J(T-); \alpha_1, f_1, \cdots, \alpha_n, f_n) = e^{-\alpha_1 J(T-)} F(\mathbf{p}_T^-; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n). \tag{4.52}$$

Combining (4.45),(4.47),(4.51) and (4.52), we arrive at

$$\begin{aligned} &F(X; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n) \\ &= \sum_{0<s<T} \sum_{m=1}^{n} e^{-\alpha_1 J(s-)} F(\mathbf{p}_s^+; \alpha_1, f_1, \cdots, \alpha_m, f_m; \alpha_{m+1}) \\ &\quad \cdot G(\theta_s\mathbf{p}; \alpha_{m+1}, f_{m+1}, \cdots, \alpha_n, f_n) + e^{-\alpha_1 J(T-)} F(\mathbf{p}_T^-; 0; \alpha_1, f_1, \cdots, \alpha_n, f_n) \end{aligned} \tag{4.53}$$

Here we compute the expectations of the random variables appearing in the last formula.

$$\mathbf{n}^+ \{F(w; \alpha_1, f_1, \cdots, \alpha_m, f_m; \alpha_{m+1})\} = \hat{\mu}_{\alpha_1}(f_1 G^0_{\alpha_2} f_2 \cdots G^0_{\alpha_{m-1}} f_{m-1} G^0_{\alpha_m} f_m u_{\alpha_{m+1}}). \tag{4.54}$$

When $m = n$, the last factor $u_{\alpha_{n+1}}$ in the above expression is understood to be $u_0 = \varphi$. In fact, the left hand side equals

$$\begin{aligned} &\mathbf{n}\left\{ \int\cdots\int_{0<t_1<\cdots<t_m<\zeta(w)} \prod_{k=1}^{m} \left(e^{-\alpha_k(t_k - t_{k-1})} f_k(w(t_k)) \right) e^{-\alpha_{m+1}(\zeta(w) - t_m)} dt_1\cdots dt_m; W_a^+ \right\} \\ &= \int\cdots\int_{0<t_1<\cdots<t_m<\infty} \mathbf{n}\left\{ \prod_{k=1}^{m} \left(e^{-\alpha_k(t_k - t_{k-1})} f_k(w(t_k)) \right) u_{\alpha_{m+1}}(w(t_m)); \zeta > t_m \right\}, \end{aligned}$$

which can be seen to coincide with the right hand side of (4.54) by (4.4).

We further have for any constant time $s > 0$,

$$E\left\{G(\theta_s\mathbf{p};\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n)\right\} = G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n). \tag{4.55}$$

On the other hand, we have in view of §4.2

$$\begin{aligned} & E\left\{F(\mathbf{p}_T^-;0;\alpha_1,f_1,\cdots,\alpha_n,f_n\right\} = L(m_0,\psi)^{-1}\mathbf{n}^-\left\{F(w;0;\alpha_1,f_1,\cdots,\alpha_n,f_n)\right\} \\ = \ & L(m_0,\psi)^{-1}\hat{\mu}_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{n-1}}f_{n-1}G^0_{\alpha_n}f_n\psi), \end{aligned}$$

$$E\left\{\int_0^T e^{-\alpha_1 J(s)}ds\right\} = \frac{1}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}, \tag{4.56}$$

$$E\left\{e^{-\alpha_1 J(T-)}\right\} = \frac{L(m_0,\psi)}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}. \tag{4.57}$$

We can now get from (4.53) that

$$\begin{aligned} & G(\alpha_1,f_1,\cdots,\alpha_n,f_n) = E\left\{F(X;0;\alpha_1,f_1,\cdots,\alpha_n,f_n)\right\} \\ = \ & \sum_{m=1}^n E\left\{\int_0^T e^{-\alpha_1 J(s)}ds\right\}\mathbf{n}^+\left\{F(w;\alpha_1,f_1,\cdots,\alpha_m;\alpha_{m+1})\right\} \\ & \times G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n) + E\left\{e^{-\alpha_1 J(T-)}\right\}E\left\{F(\mathbf{p}^-;0;\alpha_1,f_1,\cdots,\alpha_n,f_n)\right\} \\ = \ & \sum_{m=1}^{n-1}\frac{1}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}\hat{\mu}_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{m-1}}f_{m-1}G^0_{\alpha_m}f_m u_{\alpha_{m+1}}) \\ & \times G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n) + \frac{1}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}\hat{\mu}_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{n-1}}f_{n-1}G^0_{\alpha_n}f_n\varphi) \\ + \ & \frac{L(m_0,\psi)}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}L(m_0,\psi)^{-1}\hat{\mu}_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{n-1}}f_{n-1}G^0_{\alpha_n}f_n\psi) \\ = \ & \frac{1}{\alpha_1(u_{\alpha_1},\varphi)+L(m_0,\psi)}\sum_{m=1}^n\hat{\mu}_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{m-1}}f_{m-1}G^0_{\alpha_m}f_m u_{\alpha_{m+1}}) \\ & \cdot G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n). \end{aligned}$$

In the above and in what follows, we use the convention that

$$u_{\alpha_{m+1}} = G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n) = 1$$

for $m = n$. This combined with (4.1) and (4.30) eventually leads us to

$$\begin{aligned} G(\alpha_1,f_1,\cdots,\alpha_n,f_n) \ = \ & \sum_{m=1}^n G_{\alpha_1}(f_1G^0_{\alpha_2}f_2\cdots G^0_{\alpha_{m-1}}f_{m-1}G^0_{\alpha_m}f_m u_{\alpha_{m+1}})(a) \\ & \cdot G(\alpha_{m+1},f_{m+1},\cdots,\alpha_n,f_n). \end{aligned} \tag{4.58}$$

Based on this formula, we shall prove the desired identity (4.43), namely,

$$G(\alpha_1,f_1,\cdots,\alpha_n,f_n) = G_{\alpha_1}f_1G_{\alpha_2}f_2\cdots G_{\alpha_n}f_n(a) \tag{4.59}$$

by induction in n.
(1). When $n = 1$, (4.59) is just (4.30).
(2). Suppose (4.59) holds up to $n - 1$. Then

$$G(\alpha_{m+1}, f_{m+1}, \cdots, \alpha_n, f_n) = (G_{\alpha_{m+1}} f_{m+1} \cdots G_{\alpha_n} f_n)(a),$$

and (4.58) can be written as

$$\begin{aligned} G(\alpha_1, f_1, \cdots, \alpha_n, f_n) &= \sum_{m=1}^{n} G_{\alpha_1}(f_1 G^0_{\alpha_2} f_2 \cdots G^0_{\alpha_{m-1}} f_{m-1} G^0_{\alpha_m} f_m u_{\alpha_{m+1}})(a) \\ &\quad \cdot (G_{\alpha_{m+1}} f_{m+1} \cdots G_{\alpha_n} f_n)(a). \end{aligned} \tag{4.60}$$

Let us rewrite the right hand side of (4.59) by applying the formula (4.31) to the operation G_{α_2} in getting

$$\begin{aligned} (G_{\alpha_1} f_1 G_{\alpha_2} f_2 \cdots G_{\alpha_n} f_n)(a) &= (G_{\alpha_1} f_1 G^0_{\alpha_2} f_2 G_{\alpha_3} f_3 \cdots G_{\alpha_n} f_n)(a) \\ &+ (G_{\alpha_1} f_1 u_{\alpha_2})(a)(G_{\alpha_2} f_2 \cdots G_{\alpha_n} f_n)(a). \end{aligned}$$

Apply the same procedure to the operation G_{α_3} to see that the right hand side of (4.59) equals

$$\begin{aligned} & (G_{\alpha_1} f_1 G^0_{\alpha_2} f_2 G^0_{\alpha_3} f_3 G_{\alpha_4} f_4 \cdots G_{\alpha_n} f_n)(a) \\ + & (G_{\alpha_1} f_1 G^0_{\alpha_2} f_2 u_{\alpha_3})(a)(G_{\alpha_3} f_3 \cdots G_{\alpha_n} f_n)(a) \\ + & (G_{\alpha_1} f_1 u_{\alpha_2})(a)(G_{\alpha_2} f_2 \cdots G_{\alpha_n} f_n)(a). \end{aligned}$$

Repeating the same procedures, we finally find that the right hand side of (4.59) coincides with the right hand side of (4.60) as was to be proved.

(ii). For $t_1 > 0, \cdots, t_n > 0$, let

$$F(t_1, \cdots, t_n) = E\left\{ \prod_{k=1}^{n} f_k\left(X_{t_1 + \cdots + t_k}\right); \zeta_\omega > t_1 + \cdots + t_n \right\},$$

$$G(t_1, \cdots, t_n) = \left(p_{t_1} f_1 p_{t_2} f_2 \cdots p_{t_n} f_n\right)(a).$$

(4.43) is then equivalent to

$$\begin{aligned} & \int_0^\infty \cdots \int_0^\infty e^{-\alpha_1 t_1 - \cdots - \alpha_n t_n} F(t_1, \cdots, t_n) dt_1 \cdots dt_n \\ = & \int_0^\infty \cdots \int_0^\infty e^{-\alpha_1 t_1 - \cdots - \alpha_n t_n} G(t_1, \cdots, t_n) dt_1 \cdots dt_n. \end{aligned} \tag{4.61}$$

Clearly $F(t_1, \cdots, t_n)$ is right continuous. Further, by virtue of Lemma 4.11, we can easily see that $G(t_1, \cdots, t_n)$ is separately right continuous. Consequently, (4.61) implies

$$F(t_1, \cdots, t_n) = G(t_1, \cdots, t_n)$$

the desired Markov property of X. □

We add a lemma saying that the point a is regular for itself with respect to (X_t, P).

Lemma 4.12. (i) $P(\eta_a = 0) = 1, \qquad$ where $\eta_a = \inf\{t > 0 : X_t = a\}$.
(ii) $\mathbf{n}^+(W_a) = \infty$.

Proof. (i). In view of the proof of Proposition 4.3, $\lim_{t \downarrow 0} u_1(X_t) = 1$. Hence, if we put $\eta_{a,\epsilon} = \inf\{t > \epsilon : X_t = a\}$, then owing to the Markov property

$$\begin{aligned} E(e^{-\eta_a}) &= \lim_{\epsilon \downarrow 0} E(e^{-\eta_{a,\epsilon}}) \\ &= \lim_{\epsilon \downarrow 0} E(e^{-\epsilon} u_1(X_\epsilon); \zeta_\omega > \epsilon) = 1. \end{aligned}$$

(ii). By the construction of X_t, the point a is evidently instantaneous in the sense that

$$P(\tau_a = 0) = 1, \qquad \text{where } \tau_a = \inf\{t > 0 : X_t \in S_0\}.$$

Hence (i) holds if and only if the domain $D_{\mathbf{p}^+}$ of the Poisson point process $\mathbf{p}^+$ accumulates at 0 P-a.s., which is also equivalent to (ii) (cf. [15, §4]). □

4.5 A symmetric extension $\tilde{X}$ of X^0

In §4.1, we have started with an m-symmetric diffusion

$$X^0 = \left\{X_t^0,\ 0 \le t < \zeta^0,\ P_x^0,\ x \in S_0\right\}$$

on S_0, where $P_x^0,\ x \in S_0$, are probability measures on a certain sample space, say Ω^0.

In §4.2, we have constructed a continuous process

$$X = \{X_t,\ 0 \le t < \zeta_\omega,\ P\}$$

on S by piecing together the excursions, where P is a probability measure on another sample space Ω to define the excursion valued Poisson point processes.

For convenience, we assume that Ω^0 contains an extra point ω^a with $P_x^0(\{\omega^a\}) = 0,\ x \in S_0$, and we set $P_a^0 = \delta_{\omega^a}$, ω^a representing a path taking value a at any time.

We now let

$$\tilde{\Omega} = \Omega^0 \times \Omega, \qquad \tilde{P}_x = P_x^0 \times P,\ x \in S. \tag{4.62}$$

For $\tilde{\omega} = (\omega^0, \omega) \in \tilde{\Omega}$, let us define $\tilde{X}_t = \tilde{X}_t(\tilde{\omega})$ as follows:

(1) When $\omega^0 \in \Omega^0 \setminus \{\omega^a\}$,

$$\tilde{X}_t(\tilde{\omega}) = \begin{cases} X_t^0(\omega^0) & 0 \le t < \zeta^0(\omega^0) \le \sigma_a(\omega^0) \le \infty \\ X_{t-\sigma_a(\omega^0)}(\omega) & \sigma_a(\omega^0) \le t < \sigma_a(\omega^0) + \zeta_\omega, \text{ if } \sigma_a(\omega^0) < \infty. \end{cases} \tag{4.63}$$

(2) When $\omega^0 = \omega^a$,

$$\tilde{X}_t(\tilde{\omega}) = X_t(\omega) \quad 0 \le t < \zeta_\omega. \tag{4.64}$$

The life time $\tilde{\zeta}$ of $\tilde{X}_t$ is defined by

$$\tilde{\zeta} = \begin{cases} \zeta^0 & \text{if } \sigma_a(\omega^0) = \infty, \\ \sigma_a(\omega^0) + \zeta_\omega & \text{if } \sigma_a(\omega^0) < \infty. \end{cases} \tag{4.65}$$

Lemma 4.13. *$\tilde{X} = \{\tilde{X}_t, 0 \le t < \tilde{\zeta}, \tilde{P}_x, x \in S\}$ is a Markov process on S with transition function $\{p_t\}$ defined by* (4.35) *and* (4.36).

Proof. This is an easy consequence of the Markov property of (X_t^0, P_x^0) and the Markov property of (X_t, P) proved in Propisition 4.4. To see this, we put, for any $0 < s_1 < s_2 < \cdots < s_n,\ f_1, f_2, \cdots, f_n \in \mathcal{B}(S)$,

$$I_k = \tilde{E}_x\left(f_1(\tilde{X}_{s_1})\cdots f_{k-1}(\tilde{X}_{s_{k-1}})f_k(\tilde{X}_{s_k})\cdots f_n(\tilde{X}_{s_n}); s_{k-1} < \sigma_a \le s_k\right),$$

for $1 \le k \le n$ with $s_0 = 0$, and

$$J = \tilde{E}_x(f_1(\tilde{X}_{s_1})\cdots f_n(\tilde{X}_{s_n}); s_n < \sigma_a).$$

Using the definition of $\tilde{X}$, Proposition 4.4, the Markov property of X^0 and (4.36) successively, we are led to

$$\begin{aligned}
I_k &= E_x^0\left(f_1(X_{s_1}^0)\cdots f_{k-1}(X_{s_{k-1}}^0)E\left(f_k(X_{s_k-\sigma_a})\cdots f_n(X_{s_n-\sigma_a})\right); s_{k-1} < \sigma_a \le s_k\right) \\
&= E_x^0\left(f_1(X_{s_1}^0)\cdots f_{k-1}(X_{s_{k-1}}^0)p_{s_k-\sigma_a}\left(f_k p_{s_{k+1}-s_k} f_{k+1}\cdots p_{s_n-s_{n-1}}f_n\right)(a); s_{k-1} < \sigma_a \le s_k\right) \\
&= E_x^0\Big\{f_1(X_{s_1}^0)\cdots f_{k-1}(X_{s_{k-1}}^0) \\
&\quad \cdot E^0_{X^0_{s_{k-1}}}\left(p_{s_k-s_{k-1}-\sigma_a}(f_k p_{s_{k+1}-s_k} f_{k+1}\cdots p_{s_n-s_{n-1}}f_n); \sigma_a \le s_k - s_{k-1}\right); s_{k-1} < \sigma_a \le s_k\Big\} \\
&= E_x^0\Big(f_1(X_{s_1}^0)\cdots f_{k-1}(X_{s_{k-1}}^0) \\
&\quad \cdot(p_{s_k-s_{k-1}} - p^0_{s_k-s_{k-1}})(f_k p_{s_{k+1}-s_k} f_{k+1}\cdots p_{s_n-s_{n-1}}f_n)(X^0_{s_{k-1}}); s_{k-1} < \sigma_a \le s_k\Big).
\end{aligned}$$

By the Markov property of X^0, we thus get

$$\begin{aligned}
I_k &= p_{s_1}^0 f_1 \cdots p^0_{s_{k-1}-s_{k-2}} f_{k-1} p_{s_k-s_{k-1}} f_k p_{s_{k+1}-s_k} f_{k+1}\cdots p_{s_n-s_{n-1}} f_n(x) \\
&- p_{s_1}^0 f_1 \cdots p^0_{s_{k-1}-s_{k-2}} f_{k-1} p^0_{s_k-s_{k-1}} f_k p_{s_{k+1}-s_k} f_{k+1}\cdots p_{s_n-s_{n-1}} f_n(x).
\end{aligned}$$

Clearly we also have

$$J = E_x^0\left(f_1(X_{s_1}^0)\cdots f_n(X_{s_n}^0); s_n < \sigma_a\right) = p_{s_1}^0 f_1 \cdots p^0_{s_n-s_{n-1}} f_n.$$

Hence we arrive at

$$\tilde{E}_x(f_1(\tilde{X}_{s_1})f_2(\tilde{X}_{s_2})\cdots f_n(\tilde{X}_{s_n})) = \sum_{k=1}^n I_k + J = p_{s_1} f_1 p_{s_2-s_1} f_2 \cdots p_{s_n-s_{n-1}} f_n(x),$$

the desired Markov property of $\tilde{X}$. □

We now state main theorems of the present paper. In this section, we have started with an m-symmetric diffusion X^0 on S_0 satisfying conditions **A.1,A.2,A.3,A.4** and constructed a Markov process $\tilde{X}$ on S. The resolvent $\{G_\alpha\}_{\alpha>0}$ of the Markov process $\tilde{X}$ is defined by

$$G_\alpha f(x) = \tilde{E}_x\left(\int_0^\infty e^{-\alpha t} f(\tilde{X}_t)dt\right),\ f \in \mathcal{B}(S). \tag{4.66}$$

The resolvent of X^0 was denoted by G_α^0.

Theorem 4.1. *The process* $\tilde{X}$ *enjoys the following properties:*
(1) $\tilde{X}$ *is an* m*-symmetric diffusion process on* S*. It admits no killing inside* S *and is a Hunt process on* S *in the sense that*

$$\tilde{X}_{\tilde{\zeta}(\tilde{\omega})-}(\tilde{\omega}) = \Delta \quad \text{if } \tilde{\zeta}(\tilde{\omega}) < \infty.$$

(2) X^0 *is identical in law with the process obtained from* $\tilde{X}$ *by killing upon the hitting time* σ_a *of the point* a.

Further the resolvent of $\tilde{X}$ *admits the next expression for* $f \in \mathcal{B}(S)$*:*

$$G_\alpha f(x) = G^0_\alpha f(x) + u_\alpha(x) \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi)}, \ x \in S_0, \tag{4.67}$$

$$G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi)}, \tag{4.68}$$

where $L(m_0, \psi)$ *is the energy functional of the* X^0*-excessive measure* $m_0 = \varphi \cdot m$ *and the* X^0*-excessive function* $\psi = 1 - \varphi$.

Proof of Theorem 4.1. By Lemma 4.6, (4.37) and Lemma 4.13, we see that $\tilde{X}$ is a Markov process on S with the m-symmetric resolvent (4.67),(4.68).

On account of **A.1**, we may assume that

$$X^0_t(\omega^0) \text{ is continuous in } t \in [0, \zeta^0(\omega^0)) \text{ and } X_{\zeta^0(\omega^0)-}(\omega^0) = a \cup \Delta$$

for every $\omega^0 \in \Omega^0$. We have already chosen Ω in a way that

$$X_t(\omega) \text{ is continuous in } \ t \in [0, \zeta_\omega) \text{ and } X_0(\omega) = a.$$

Hence the path $\tilde{X}_\cdot(\tilde{\omega})$ defined by (4.63),(4.64),(4,65) is continuous on $[0, \tilde{\zeta})$.

Consider a function $u = G_\alpha f$ on S for $f \in C_b(S)$. By the assumptions **A.2,A.3** and the expression (4.67),(4.68), $u(X^0_t(\omega^0))$ is then continuous in $t \in [0, \sigma_a)$ for any $\omega^0 \in \Omega^0$. By the proof of Proposition 4.3, $u(X_t(\omega))$ is continuous in $t \in [0, \zeta_\omega)$ for any $\omega \in \Omega$. Hence $u(\tilde{X}_t(\tilde{\omega}))$ is right continuous in $t \in [0, \tilde{\zeta}(\tilde{\omega}))$ for any $\tilde{\omega} \in \tilde{\Omega}$. (In view of (4.33), we even know that $u(\tilde{X}_t)$ is continuous in $t \in [0, \tilde{\zeta})$ $\tilde{P}_x$-a.s. for any $x \in S$). Therefore we can conclude that $\tilde{X}$ is a strong Markov process with continuous sample paths, namely, a diffusion process on S (cf.[2]). Clearly $\tilde{X}$ is of no killing inside S and a Hunt process on S. The property **(2)** is also evident from the construction of $\tilde{X}$. □

Remark 4.1. A prime reason for us to impose a regularity condition **A.4** on the given process X^0 on S_0 is in that it implies an important property in Lemma 4.3 of the excursion law **n** of (4.4), which is essential in deriving the continuity near the point a of the process X constructed in §4.2.

Given a standard process $\tilde{X}$ on S for which the point a is recurrent, K.Itô [15] assoicated with $\tilde{X}$ a Poisson point process **p** of excursions in the manner of §3.1 and gave a list of necessary conditions for the charactersitic measure **n** of **p** should obey. Conversely T.S. Salisbury [25], [26] constructed a right process on S for which a is recurrent by means of X^0 and an excusion law **n** satisfying Itô's conditions being strengthened by adding the property as in Lemma 4.3 and some others.

Remark 4.2. By invoking the work of P.A. Meyer[20] on the absorbed Poisson point process and by adopting a similar argument to §4.2, we can show that Theorem 3.1 of §3.1 remains true without assuming condition **B.3** on the recurrence of the point $\{a\}$.

In this general case, the right continuous inverse $S(s)$ of the local time $L(t)$ at $\{a\}$ of the given process X on S is defined for $s \geq L(\infty)$ as $S(L(\infty)) = \infty$, and we see from Lemma 2.3 and by letting $\alpha \downarrow 0$ in (2.21) that $L(\infty)$ has an exponetial distribution with mean $L(m_0, \psi)^{-1}$.

Let

$$\begin{aligned} D_{\mathbf{p}} &= \{s : S(s) - S(s-) > 0\}, \\ \mathbf{p}_s(t) &= X_{S(s-)+t}, \ s \in D_{\mathbf{p}}, \ 0 \leq t < S(s) - S(s-). \end{aligned}$$

Then $D_{\mathbf{p}} \subset (0, L(\infty)],\ L(\infty) \in D_{\mathbf{p}}$ and $\{\mathbf{p}_s, s > 0\}$ is a point process with values in the space W_a defined by (4.13) instead of (3.6). Moreover, if we define the spaces W_a^+, W_a^- by (4.14), (4.15) respectively, then

$$\mathbf{p}_s \in W_a^+ \text{ for } s \in D_{\mathbf{p}} \cap (0, L(\infty)), \quad \mathbf{p}_{L(\infty)} \in W_a^-.$$

By Theorem 5 of Meyer[20], $\{\mathbf{p}_s,\ s > 0\}$ is an *absorbed Poission point process.* More precisely, on a certain probability space $(\tilde{\Omega}, \tilde{P})$, there is a Poisson point process $\{\tilde{\mathbf{p}}_s, s > 0\}$ on W_a with domain $D_{\tilde{\mathbf{p}}}$ and with the following properties.
(a) Let $\tilde{\zeta} = \inf\{s > 0 : \tilde{\mathbf{p}}_s \in W_a^-\}$ and consider the stopped point process $\{\bar{\mathbf{p}}, s > 0\}$:

$$\bar{\mathbf{p}}_s = \tilde{\mathbf{p}}_s \text{ for } s \in D_{\bar{\mathbf{p}}} = D_{\tilde{\mathbf{p}}} \cap (0, \tilde{\zeta}].$$

Then the point process $\{\mathbf{p}_s, s > 0\}$ and $\{\bar{\mathbf{p}}_s, s > 0\}$ are equivalent in law.
(b) Let $\mathbf{n}$ be the characteristic measure of $\{\tilde{\mathbf{p}}_s, s > 0\}$. Then $\{w(t), \mathbf{n}\}$ is Markovian with respect to the transition funtion p_t^0 of X^0. Let $\{\nu_t\}$ be the entrance law associated with $\mathbf{n}$. Then ν_t is a finite measure for each $t > 0$ and $\int_0^\infty e^{-t}\nu_t dt$ has a total mass not greater than 1.

We now prove that Theorem 3.1 *remains valid for this* $\{\nu_t\}$ *and for the entrance law* $\{\mu_t\}$ *specified by the equation* (2.22).

Take a bounded Borel function f on S and define $\hat{f}_\alpha(w),\ w \in W_a,\ \alpha > 0$, as in the proof of Proposition 4.2. We have, almost surely with respect to P_a,

$$\begin{aligned} \int_0^\zeta e^{-\alpha t} f(X_t)dt &= \sum_{s<L(\infty)} \int_{S(s-)}^{S(s)} e^{-\alpha t} f(X_t)dt + \int_{S(L(\infty)-)}^\infty e^{-\alpha t} f(X_t)dt \\ &= \sum_{s<L(\infty)} e^{-\alpha S(s-)} \hat{f}_\alpha(\mathbf{p}_s) + e^{-\alpha S(L(\infty)-)} \hat{f}_\alpha(\mathbf{p}_{L(\infty)}), \end{aligned}$$

which is equivalent in law to

$$\sum_{s<\tilde{\zeta}} e^{-\alpha \tilde{S}(s-)} \hat{f}_\alpha(\tilde{\mathbf{p}}_s^+) + e^{-\tilde{S}(\tilde{\zeta}-)} \hat{f}_\alpha(\tilde{\mathbf{p}}_{\tilde{\zeta}}), \tag{4.69}$$

where $\{\tilde{\mathbf{p}}_s^+, s > 0\}$ is a Poisson point process defined by $\tilde{\mathbf{p}}_s^+ = \tilde{\mathbf{p}}_s$ for $s \in D_{\tilde{\mathbf{p}}^+} = D_{\tilde{\mathbf{p}}} \cap \{s : \tilde{\mathbf{p}}_s \in W_a^+\}$ and $\tilde{S}(s) = \sum_{r \leq s} \zeta(\tilde{\mathbf{p}}_r^+)$. The characteristic measure of $\{\tilde{\mathbf{p}}_s^+, s > 0\}$ is the restriction $\mathbf{n}^+$ of $\mathbf{n}$ on W_a^+. In the same way as in the proof of Lemma 4.5, we can prove that

$$\tilde{E}(e^{-\alpha\tilde{S}(s)}) = \exp(-\alpha\hat{\nu}_\alpha(\varphi)), \quad \hat{\nu}_\alpha = \int_0^\infty e^{-\alpha t}\nu_t dt.$$

Now the value $G_\alpha f(a)$ equals the expectation of the random variable (4.69) with respect to $\tilde{P}$, which can be evaluated by taking into account of the following facts.
(i) The three objects $\{\tilde{\mathbf{p}}_s^+, s > 0\}$, $\tilde{\zeta}$ and $\tilde{\mathbf{p}}_{\tilde{\zeta}}$ are independent.
(ii) $\tilde{\zeta}$ has an exponential distribution with mean $L(m_0, \psi)^{-1}$.
(iii) The law of $\tilde{\mathbf{p}}_{\tilde{\zeta}}$ is $L(m_0, \psi)^{-1}\mathbf{n}^-$ where $\mathbf{n}^-$ is the restriction of $\mathbf{n}$ on W_a^-.

Indeed, exactly the same computation as in the proof of Propostion 4.2 leads us to

$$G_\alpha f(a) = \frac{\hat{\nu}_\alpha(f)}{\alpha\hat{\nu}_\alpha(\varphi) + L(m_0, \psi)}, \tag{4.70}$$

which combined with (2.15) and Lemma 2.2 (ii) yields

$$\frac{\hat{\nu}_\alpha(f)}{\alpha\hat{\nu}_\alpha(\varphi) + L(m_0, \psi)} = \frac{\hat{\mu}_\alpha(f)}{\alpha\hat{\mu}_\alpha(\varphi) + L(m_0, \psi)}$$

Therefore for each $\alpha > 0$ there is a constant c_α such that $\hat{\nu}_\alpha = c_\alpha\hat{\mu}_\alpha$. Inserting this into the above equation, we easily obtain $c_\alpha = 1$ and so $\nu_t = \mu_t,\ t > 0$.

5 Uniqueness of the symmetric extension and expression of its Dirichlet form

In the preceding section, we have started with an m-symmetric diffusion X^0 on S_0 satisfying conditions **A.1,A.2,A.3,A.4**, and constructed a process $\tilde{X}$ on S satisfying properties **(1),(2)** stated in Theorem 4.1. Let us call a process on S satisfying conditions **(1),(2)** *a symmetric extension of* X^0. In this section, we are concerned with the uniqueness of a symmetric extension of X^0 and explicit expression of its Dirichlet form on $L^2(S; m)$. We aim at proving the following:

Theorem 5.1. *Assume that an m-symmetric diffusion X^0 on S_0 satisfies conditions* **A.1,A.2.** *Let $\hat{X}$ be a symmetric extension of X^0 and $(\mathcal{E}, \mathcal{F})$ be the Dirichlet form on $L^2(S; m)$ of $\hat{X}$.*
(i) *$\hat{X}$ admits the resolvent identical with* (4.67),(4.68)*.*
(ii) *$(\mathcal{E}, \mathcal{F})$ admits the expression*

$$\mathcal{F}_e = \{w = u_0 + c\varphi : u_0 \in \mathcal{F}_{o,e},\ c \text{ constant}\}, \quad \mathcal{F} = \mathcal{F}_e \cap L^2(S; m), \tag{5.1}$$

$$\mathcal{E}(w, w) = \mathcal{E}(u_0, u_0) + c^2\mathcal{E}(\varphi, \varphi), \quad \mathcal{E}(\varphi, \varphi) = L(m_0, \psi), \tag{5.2}$$

where $(\mathcal{F}_{0,e}, \mathcal{E})$ is the extended Dirichlet space of X^0 and $L(m_0, \psi)$ is the energy functional of $m_0 = \varphi \cdot m$ and ψ with respect to X^0.
(iii) *X^0 satisfies* **(A.3)** *automatically: $u_\alpha \in L^1(S; m),\ \alpha > 0$.*
(iv) $\hat{P}_a(\sigma_a = 0,\ \tau_a = 0) = 1$
where $\sigma_a = \inf\{t > 0 : X_t = a\}, \quad \tau_a = \inf\{t > 0 : X_t \in S_0\}$.
(v) *$(\mathcal{E}, \mathcal{F})$ is irreducible.*

Corollary 5.1. *Under the conditions* **A.1,A.2** *for an m-symmetric diffusion X^0 on S_0, the symmetric extension of X^0 is unique in law.*

Corollary 5.1 follows from Theorem 5.1 (i). We prepare a lemma before the proof of Theorem 5.1.

Assume that $X = (X_t, P_x)$ is an m-symmetric Hunt process on S and $(\mathcal{E}, \mathcal{F})$ is the associated Dirichlet form on $L^2(S; m)$. No regularity for the Dirichlet form $(\mathcal{E}, \mathcal{F})$ is assumed in advance.

In accordance with [19], we set for a closed set $F \subset S$,

$$\mathcal{F}_F = \{u \in \mathcal{F} : u = 0 \quad m\text{-a.e. on } S \setminus F\},$$

and call an increasing family $\{F_n\}$ of closed subsets of S an $\mathcal{E}$-*nest* if the space $\cup_{n=1}^{\infty} \mathcal{F}_{F_n}$ is $\mathcal{E}_1$-dense in $\mathcal{F}$. A set N is called $\mathcal{E}$-*exceptional* if $N \subset \cap_{n=1}^{\infty} F_n^c$ for some $\mathcal{E}$-nest $\{F_n\}$. On the other hand, we call a set $N \subset S$ an X-*exceptional set* if there exists a Borel set $B_1 \supset B$ with

$$P_m(\sigma_{B_1} < \infty) = 0.$$

A nearly Borel set $N \subset S$ is called X-*properly exceptional* if $m(N) = 0$ and $S \setminus N$ is X-invariant in the sense that

$$P_x(X_t \in S_\Delta \setminus N \text{ or } X_{t-} \in S_\Delta \setminus N \ \exists t \geq 0) = 1, \ \forall x \in S \setminus N.$$

Lemma 5.1. (i) *The following properties of a set $N \subset S$ are equivalent each other:*
α. N is $\mathcal{E}$-exceptional.
β. N is X-exceptional.
γ. N is contained in an X-properly exceptional Borel set.

(ii) *If $\{F_n\}$ is an $\mathcal{E}$-nest, then*

$$P_x\left(\lim_{n\to\infty} \sigma_{S\setminus F_n} \geq \zeta\right) = 1 \quad \text{q.e.,} \tag{5.3}$$

where q.e. *means 'except on a set $N \subset S$ satisfying one of the properties in* (i) *'.*
(iii) *$(\mathcal{E}, \mathcal{F})$ is a quasi-regular Dirichlet form on $L^2(S; m)$ in the sense of [19, §IV 3].*

Proof. (i). The equivalences $\alpha \Leftrightarrow \beta$ and $\beta \Leftrightarrow \gamma$ were proved in [19, Th.5.29] and in [9, Th.4.1.1] respectively.

(ii). Put $\sigma = \lim_{n\to\infty} \sigma_{S\setminus F_n}$. On account of [19, Th.2.11, Th.5.4], we have for a strictly positive bounded m-integrable function f on S,

$$E_x\left(\int_{\sigma\wedge\zeta}^{\zeta} e^{-s} f(X_s) ds\right) = 0 \quad m\text{−a.e. } x \in S.$$

Since the function of x on the left hand side of the above equation is X-excessive, it is finely continuous on S and hence the above equation holds q.e. by [9, Lemma 4.1.5].

(iii) Since $(\mathcal{E}, \mathcal{F})$ is associated with a Hunt process X, it must be quasi-regular by virtue of [19, Th.5.1]. □

Proof of Theorem 5.1. Since $\hat{X}$ is not only a diffusion process but also a Hunt process on S, the Dirichlet form $(\mathcal{E}, \mathcal{F})$ of $\hat{X}$ is quasi-regular by the above lemma.

Consequently we can invoke [3, Th.3.7] to find a regular Dirichlet space $(S', m', \mathcal{F}', \mathcal{E}')$ related to the quasi-regular Dirichlet space $(S, m, \mathcal{F}, \mathcal{E})$ by a quasi-homeomorphism q: there exist an $\mathcal{E}$-nest $\{F_n\}$ on S and an $\mathcal{E}'$-nest $\{F'_n\}$ on S' such that q is a one to one mapping from $S_1 = \cup_{n=1}^{\infty} F_n$ onto $S'_1 = \cup_{n=1}^{\infty} F'_n$ and its restriction on each F_n is homeomorphic to F'_n. Further, m' is the image measure of m by q and the space $(\mathcal{F}', \mathcal{E}')$ is also the image of $(\mathcal{F}, \mathcal{E})$ by q. Thus, if we put $(\Phi u)(x') = u(q^{-1}(x')),\ x' \in S'_1$, then

$$\int_{S'} (\Phi u) dm' = \int_S u dm,\ \forall u \geq 0;\ \mathcal{F}' = \Phi(\mathcal{F}),\ \mathcal{E}'(\Phi u, \Phi v) = \mathcal{E}(u, v),\ u, v \in \mathcal{F}. \qquad (5.4)$$

We note that $S \setminus S_1$ (resp. $S' \setminus S'_1$) is $\mathcal{E}-$(resp. $\mathcal{E}'-$)exceptional and, when $N' = q(N)$, N is $\mathcal{E}$-exceptional if and only if N' is $\mathcal{E}'$-exceptional (cf.[3, Cor.3.6].)

For a Borel set $B \subset S$, we denote by B_Δ the subset $B \cup \Delta$ of S_Δ with induced topology. The above q can then be extended to a homeomorphism between $(F_n)_\Delta$ and $(F'_n)_{\Delta'}$ for each n, where Δ' denotes the point at infnity of S' (which is added as an isolated point when S' is compact).

We now apply Lemma 5.1 to the above $\mathcal{E}$-nest $\{F_n\}$ in finding an $\hat{X}$-properly exceptional Borel set $\hat{N} \subset S$ containing $S \setminus S_1$ such that (5.3) holds for any $x \in S \setminus \hat{N}$. q is then a one to one mapping between $S \setminus \hat{N}$ and $S' \setminus \hat{N}'$, where

$$\hat{N}' = (S' \setminus S'_1) \cup q(S \cap \hat{N}).$$

In view of condition **A.2** for X^0, condition **(2)** for $\hat{X}$ and the above observation, the one point set $\{a\}$ is not $\hat{X}$-exceptional and consequently it is not $\mathcal{E}$-exceptional by virtue of Lemma 5.1. Therefore a must be located in $S \setminus \hat{N}$ and furthermore

$$\{a'\} \text{ is not } \mathcal{E}' - \text{exceptional}, \qquad (5.5)$$

where $a' = q(a) \subset S' \setminus \hat{N}'$.

The restriction of $\hat{X}$ to $S \setminus \hat{N}$ is a diffusion with no killing inside $S \setminus \hat{N}$ and we denote it again by

$$\hat{X} = \left(\Omega, \mathcal{F}_t, \hat{X}_t, \hat{\zeta}, \hat{P}_x\right).$$

Let us transfer $\hat{X}$ to a process

$$\hat{X}' = \left(\Omega, \mathcal{F}_t, \hat{X}'_t, \hat{\zeta}', \hat{P}'_x\right)$$

on $S' \setminus \hat{N}'$ by the mapping q:

$$\hat{X}'_t(\omega) = q(\hat{X}_t)(\omega), \quad \hat{\zeta}'(\omega) = \hat{\zeta}(\omega), \quad \omega \in \Omega,\ t \geq 0,$$

$$\hat{P}'_x(\Lambda) = \hat{P}_{q^{-1}x}(\Lambda) \quad x \in S' \setminus \hat{N}',\ \Lambda \in \mathcal{F}_\infty.$$

We may extend the state space of $\hat{X}'$ to S' by making each point of $\hat{N}'$ trap. It is then easy to see that $\hat{X}'$ is a diffusion process on S' with no killing inside S' in the sense that

$$\hat{P}'_x\left(\hat{\zeta}' < \infty, \hat{X}'_{\hat{\zeta}'-} = \Delta\right) = \hat{P}'_x(\hat{\zeta}' < \infty). \qquad (5.6)$$

Further $\hat{X}'$ is associated with the Dirichlet form $(\mathcal{E}', \mathcal{F}')$ which is regular. Since $\hat{X}'$ is a diffusion without killing inside S', $(\mathcal{E}', \mathcal{F}')$ must be strongly local (cf.[9, Th.4.5.3]).

By (5.5) and Lemma 5.1, we see that the one point set $\{a'\}$ is not $\hat{X}'$-exceptional and consequently it has a positive capacity with respect to $(\mathcal{E}', \mathcal{F}')$ in virtue of [9, Th.4.2.1].

Therefore $(\mathcal{E}', \mathcal{F}')$ and $\hat{X}'$ fit the setting of §2 and they satisfy all the properties stated in Theorem 2.1 of §2. In particular, we have the next expressions of the resolvent and $(\mathcal{E}', \mathcal{F}')$ of $\hat{X}'$ in terms of the part $\hat{X}'^{,0}$ of $\hat{X}'$ on $S'_0 = S' \setminus \{a'\}$: if we denote the transition function and the resolvent of $\hat{X}'$ (resp. $\hat{X}'^{,0}$) by $p'_t,\ G'_\alpha$ (resp. $p'^{,0}_t,\ G'^{,0}_\alpha$), then

$$G'_\alpha g(a') = \frac{(u'_\alpha, g)_{m'}}{\alpha(u'_\alpha, \varphi')_{m'} + L'(m'_0, \psi')} \tag{5.7}$$

$$\mathcal{E}'(\varphi', \varphi') = L'(m'_0, \psi'), \tag{5.8}$$

where φ' (resp. u'_α) is the hitting (resp. α-order hitting) probability of $\{a'\}$ of the process $\hat{X}'$, $\psi' = 1 - \varphi'$ and

$$L'(m'_0, \psi') = \lim_{t \downarrow 0} \frac{1}{t}(\varphi' - p'^{,0}_t \varphi', \psi')_{m'}. \tag{5.9}$$

Notice that the part $(\mathcal{E}', \mathcal{F}'_0)$ of $(\mathcal{E}', \mathcal{F}')$ on S'_0 is associated with $\hat{X}'^{,0}$ which can be sent from X^0 on S_0 by the mapping q in the same way as above on account of the property **(2)** of $\hat{X}$. Hence we have for $x \in S' \setminus \hat{N}'$

$$\begin{aligned} \Phi(G_\alpha f)(x) &= G'_\alpha(\Phi f)(x),\ \Phi(G^0_\alpha f)(x) = G'^{,0}_\alpha(\Phi f)(x),\ \Phi(p^0_t f)(x) = p'^{,0}_t(\Phi f)(x), \\ \Phi(\varphi)(x) &= \varphi'(x), \quad \Phi(u_\alpha)(x) = u'_\alpha(x). \end{aligned} \tag{5.10}$$

(5.4),(5.7),(5.8),(5.9) and (5.10) now imply $L'(m'_0, \psi') = L(m_0, \psi)$ and furthermore

$$\mathcal{E}(\varphi, \varphi) = L(m_0, \psi), \quad G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, \varphi) + L(m_0, \psi)}. \tag{5.11}$$

We have obtained the expression (4.68) of the resolvent G_α of $\hat{X}$. It then satifies (4.67) for all $x \in S_0$ because of the property **(2)** of $\hat{X}$. We can also readily get the assertions (ii) and (iii) of Theorem 5.1 using (5.4) and (5.10). As for (iv), we have obviously

$$\hat{P}_a(\sigma_a = 0,\ \tau_a = 0) = \hat{P}'_{a'}(\sigma_{a'} = 0, \tau_{a'} = 0),$$

and the right hand side equals 1 by virtue of Theorem 2.1. From the expression (4.67) of the resolvent of $\hat{X}$, we have

$$(I_A, G_\alpha I_B) > 0 \quad \text{for any } A, B \in \mathcal{B}(S) \text{ with } m(A) > 0,\ m(B) > 0.$$

This property is equivalent to the irreducibility of the Dirichlet form $(\mathcal{E}, \mathcal{F})$ proving (v). □

Remark 5.1. For the symmetric extension $\tilde{X}$ of X^0 constructed in §4, not only the expression (4.67),(4.68) of its resolvent but also the property (iv) in Theorem 5.1 have been directly proved in Lemma 4.12.

6 Examples

Example 6.1. Let X be the Brownian motion on $\mathbb{R}$, X^0 be the absorbed Brownian motion on $\mathbb{R} \setminus \{0\}$ and m be the Lebesgue measure dx on $\mathbb{R}$. Then X is the unique m-symmetric extension of X^0 (in the sense that X satisfies conditions **(1),(2)** of Theorem 4.1) in accordance with Corollary 5.1.

Let $L(t)$ be the local time of X at 0 and Z be an independent exponential random variable with mean δ^{-1}. The process X_δ obtained from X killed upon the first time that $L(t) \geq Z$ is a diffusion process extending X^0 but not a symmetric extension of X^0 in the present sense because it violates the above condition **(1)**.

For $\gamma > 0$, let X^γ be the process on $\mathbb{R}$ obtained from X by a time change with respect to the inverse of its additive functional $t + \gamma L(t)$. X^γ is then a diffusion on $\mathbb{R}$ with a canonical scale $2dx$ and the speed measure $m(dx) = dx + \gamma\delta_0(dx)$. X^γ extends X^0 but violates our assumption that $m(\{0\}) = 0$.

The resolvents and Dirichlet forms of $X_\delta,\ X^\gamma$ have been exhibited in Remark 2.2.

Example 6.2. Let D be a bounded open set in $\mathbb{R}^d$, $(d \geq 1)$, and $L^2(D)$ be the L^2-space based on the Lebesgue measure on D. Denote by $H_0^1(D)$ the closure of $C_0^1(D)$ in the Sobolev space

$$H^1(D) = \{u \in L^2(D) : \frac{\partial u}{\partial x_i} \in L^2(D),\ 1 \leq i \leq n\}$$

and put

$$\mathbf{D}(u,v) = \int_D \nabla u \cdot \nabla v(x)dx, \quad u,v \in H_0^1(D).$$

Then $(\frac{1}{2}\mathbf{D}, H_0^1(D))$ is a strongly local Dirichlet form on $L^2(D)$ satisfying the Poincaré inequality (3.13). The associated symmetric diffusion $X^0 = (X_t^0, 0 \leq t < \zeta^0, P_x^0)$ on D is the absorbing Brownian motion.

Let $D^* = D \cup \{a\}$ be the one point compactification of D. Regarding D as a subspace of D^*, we have then

$$\varphi(x) = P_x^0(\zeta^0 < \infty, X_{\zeta^0-}^0 = a) = 1, \quad \psi(x) = 1 - \varphi(x) = 0,\ \forall x \in D, \tag{6.1}$$

$$u_\alpha(x) = E_x^0(e^{-\alpha\zeta^0}; X_{\zeta^0-}^0 = a) \text{ is continuous in } x \in D,\ (\alpha > 0). \tag{6.2}$$

Obviously $u_\alpha \in L^1(D)$. Hence conditions **A.1,A.2,A.3,A.4** are satisfied by X^0 and we can construct a diffusion $\tilde{X}$ on D^* as in §4. By virtue of Theorem 4.1, the resolvent of $\tilde{X}$ is expressed as

$$G_\alpha f(x) = G_\alpha^0 f(x) + u_\alpha(x)\frac{(u_\alpha, f)}{\alpha(u_\alpha, 1)},\ x \in D,\ G_\alpha f(a) = \frac{(u_\alpha, f)}{\alpha(u_\alpha, 1)},$$

and in particular, $\tilde{X}$ is conservative.

$L^2(D^*)$ denotes the L^2-space based on the 0-extension of the Lebesgue measure on D to D^*. By virtue of Theorem 4.1 and Theorem 5.1, $\tilde{X}$ is symmetric with respect to this measure and its Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(D^*)$ is describable as

$$\mathcal{F} = H_0^1(D) + \text{ constant functions on } D^*, \tag{6.3}$$

$$\mathcal{E}(w_1, w_2) = \frac{1}{2}\mathbf{D}(f_1, f_2),\ w_i = f_i + c_i,\ f_i \in H_0^1(D),\ c_i \text{ constant},\ i = 1, 2. \tag{6.4}$$

On account of Theorem 3.2 and a related observation in §3.1, this is a regular, strongly local and irreducible recurrent Dirichlet form. This Dirichlet form first appeared in [8].

The entrance law $\{\mu_t\}_{t>0}$ governing the charactersitic measure of the excursion valued Poisson point process attached to $\tilde{X}$ is given by

$$\mu_t(B)dt = \int_B P_x^0(\zeta^0 \in dt)dx, \qquad B \in \mathcal{B}(D) \tag{6.5}$$

in view of (3.9). Let $D = \cup_i D_i$ be the decomposition of the open set D into connected components. The above identity tells us that the sample path of $\tilde{X}$ entering from the point a is distributed among $\{D_i\}$ proportionally to their volumes and enters in D_i according to the restriction of μ_t to D_i. As was observed in §3.1, $\tilde{X}$ is irreducible recurrent.

According to (2.24), the Lévy measure of the inverse local time of $\tilde{X}$ at the point a is given by $-d\mu_t(D)$.

Example 6.3. We consider a finite number of disjoint rays $\ell_i, i = 1, \cdots, N$, on $\mathbb{R}^2$ merging at a point $a \in \mathbb{R}^2$. Each ray ℓ_i is homeomorphic to the open half line $(0, \infty)$ and the point a is the boundary of each ray at 0-side. We put

$$S_0 = \sum_{i=1}^{N} \ell_i, \qquad S = S_0 + a.$$

S is endowed with the induced topology as a subset of $\mathbb{R}^2$.

Let m be a positive Radon measure on S_0 with Supp$[m] = S_0$. m is extended to S by setting $m(\{a\}) = 0$. The restriction of m to ℓ_i is denoted by m_i. For any function g on S_0, its restriction to ℓ_i will be denoted by g_i. We consider a diffusion process $X^0 = \{X_t^0, \zeta^0, P_x^0\}$ on S_0 such that its restriction $X^{0,i}$ to each open half line $\ell_i \sim (0, \infty)$ is the absorbing diffusion governed by the speed measure m_i and a canonical scale, say s_i.

We notice that X^0 satisfies **A.2,A.3** if and only if 0 is a regular boundary in Feller's sense for each diffusion $X^{0,i}$ on $\ell_i,\ 1 \le i \le N$. Indeed,**A.2** holds if and only if 0 is exit (in the terminology used by [16]). If 0 is additionally non-entrance, then $m_i((0,1)) = \infty$ and **A.3** is not satisfied. If 0 is regular, then $m_i((0,1)) < \infty$ and $u_{\alpha,i}$ is m_i integrable on $(0,1)$, while $u_{\alpha,i}$ is always m_i-integrable on $[1, \infty)$ (cf.[16, p 130].)

Thus we assume that 0 is regular for every $X^{0,i}$ so that **A.1,A.2,A.3** are satisfied by X^0. **A.4** is also clearly satisfied. m is finite on any compact neighbourhood of a.

Therefore, a diffusion $\tilde{X}$ on S can be constructed as in §4 and it is a unique m-symmetric extension of X^0 with no killing inside S according to Theorem 5.1. The resolvent of $\tilde{X}$ has the expression

$$G_\alpha f(a) = \frac{\sum_i (u_{\alpha,i}, f_i)_{m_i}}{\alpha \sum_i (u_{\alpha,i}, \varphi_i)_{m_i} + \sum_i L(\varphi_i \cdot m_i, \psi_i)}.$$

The Dirichlet form $(\mathcal{E}, \mathcal{F})$ of $\tilde{X}$ on $L^2(S; m)$ is regular, strongly local, irreducible and can be described as follows:

$$\mathcal{F}_e = \{w = u_0 + c\varphi : u_0 \in \mathcal{F}_{0,e},\ c \text{ constant}\},$$

$$\mathcal{E}(w, w) = \mathcal{E}(u_0, u_0) + c^2 \mathcal{E}(\varphi, \varphi),$$

$$\mathcal{E}(\varphi,\varphi) = \sum_i L(\varphi_i \cdot m_i, \psi_i),$$

where

$$\mathcal{F}_{0,e} = \{u : u_i \text{ is absolutely continuous with respect to } s_i,$$
$$\int_0^\infty \left(\frac{du_i}{ds_i}\right)^2 ds_i < \infty,\ u_i(0) = 0,\ u_i(\infty) = 0, \text{ whenever } \infty \text{ is regular}, 1 \le i \le n\},$$

$$\mathcal{E}(u,u) = \sum_i \int_0^\infty \left(\frac{du_i}{ds_i}\right)^2 ds_i \qquad u \in \mathcal{F}_{0,e}.$$

Related Dirichlet forms and diffusions first appeared in [13].

The entrance law from a is describable as

$$\mu_t(f)dt = \sum_i P^{0,i}_{f_i\cdot m_i}\left(\zeta^{0,i} \in dt,\ X^{0,i}_{\zeta^{0,i}-} = 0\right). \tag{6.6}$$

We have a freedom of choice of the entrance law (6.6) in the following sense. Choose any positive numbers $\{p_1, \cdots, p_N\}$ and observe that the absorbed diffusion X^0 on S_0 is unchanged if we replace $m_i, s_i,\ 1 \le i \le N$, by

$$\hat{m}_i = p_i \cdot m_i, \quad \hat{s}_i = p_i^{-1} \cdot s_i, \quad 1 \le i \le N,$$

respectively. Let $\hat{m}$ be the measure on S whose restriction to ℓ_i equals $\hat{m}_i$ for each $i = 1, 2, \cdots, N$, with $\hat{m}(\{a\}) = 0$. Then we can consider the $\hat{m}$-symmetric extension $\hat{X}$ of X^0 whose entrance law $\hat{\mu}$ from a is given by (6.6) but with the replacement of m_i by $\hat{m}_i$ for $1 \le i \le N$.

Example 6.4. Let G_1, G_2 be open sets of $\mathbb{R}^d,\ (d \ge 1)$, such that

$$\overline{G}_1 \subset G_2, \qquad \overline{G}_1 \text{ is compact.}$$

We let $S_0 = G_2 \setminus \overline{G}_1$. We consider the space $S = S_0 \cup \{a\}$ equipped with the topology where a set U containing a is defined to be an open set if

$$U \setminus \{a\} = \ \left\{\text{open subset of } G_2 \text{ containing } \overline{G}_1\right\} \ \setminus \ \overline{G}_1.$$

Let X^0 be the absorbing Brownian motion on S_0. Then conditions **A.1,A.2,A.3,A.4** are satisfied by X^0. **A.3** can be verified by a comparison with the Brownian motion on $\mathbb{R}^d$.

Let m be the Lebesgue measure on S_0 extended to S by $m(\{a\}) = 0$. Let $\tilde{X}$ be the m-symmetric diffusion on S as is constructed in §4. Then, by Theorem 5.1, its Dirichlet form $(\mathcal{E}, \mathcal{F})$ on $L^2(S; m)$ is expressed as

$$\mathcal{F} = \mathcal{F}_e \cap L^2(S; m), \quad \mathcal{F}_e = \{w = u_0 + c\varphi : u_0 \in H^1_{0,e}(S_0),\ c \text{ constant}\},$$

$$\mathcal{E}(w,w) = \frac{1}{2}\mathbf{D}(u_0,u_0) + c^2 L(\varphi \cdot m, \psi),$$

where $H^1_{0,e}(S_0)$ denotes the extended Dirichlet space of $H^1_0(S_0)$.

$(\mathcal{E}, \mathcal{F})$ is a quasi-regular Dirichlet form on $L^2(S; m)$ but may not be regular. It is a regular Dirichlet space if each point of ∂G_1 is a regular boundary point of S_0 with respect to the Dirichlet problem for $(\alpha - \frac{1}{2}\Delta)$ on S_0.
